Developer Guide

AWS SDK for Go v2

AWS SDK for Go v2: Developer Guide

Table of Contents

What is the AWS SDK for Go v2?

The AWS SDK for Go v2 provides APIs and utilities that developers can use to build Go applications that use AWS services, such as Amazon Elastic Compute Cloud (Amazon EC2) and Amazon Simple Storage Service (Amazon S3).

The SDK removes the complexity of coding directly against a web service interface. It hides a lot of the lower-level plumbing, such as authentication, request retries, and error handling.

The SDK also includes helpful utilities. For example, the Amazon S3 download and upload manager can automatically break up large objects into multiple parts and transfer them in parallel.

Use the AWS SDK for Go Developer Guide to help you install, configure, and use the SDK. This guide provides configuration information, sample code, and an introduction to the SDK utilities.

Maintenance and support for SDK major versions

For information about maintenance and support for SDK major versions and their underlying dependencies, see the following in the AWS SDKs and Tools Reference Guide:

- AWS SDKs and tools maintenance policy
- AWS SDKs and tools version support matrix

Get started with AWS SDK for Go

The AWS SDK for Go requires Go 1.20 or later. You can view your current version of Go by running the following command:

```
go version
```

For information about installing or upgrading your version of Go, see https://golang.org/doc/install.

Get an Amazon Account

Before you can use the AWS SDK for Go v2, you must have an Amazon account. See How do I create and activate a new AWS account? for details.

Install the AWS SDK for Go v2

The AWS SDK for Go v2 uses Go modules, which was a feature introduced in Go 1.11. Initialize your local project by running the following Go command.

```
go mod init example
```

After initializing your Go module project, you will be able to retrieve the SDK and its required dependencies using the `go get` command. These dependencies will be recorded in the `go.mod` file which was created by the previous command.

The following commands show how to retrieve the standard set of SDK modules to use in your application.

```
go get github.com/aws/aws-sdk-go-v2
go get github.com/aws/aws-sdk-go-v2/config
```

This will retrieve the core SDK module, and the config module which is used for loading the AWS shared configuration.

Next you can install one or more AWS service API clients required by your application. All API clients are located under `github.com/aws/aws-sdk-go-v2/service` import hierarchy. A

complete set of currently supported API clients can be found here. To install a service client, execute the following command to retrieve the module and record the dependency in your `go.mod` file. In this example we retrieve the Amazon S3 API client.

```
go get github.com/aws/aws-sdk-go-v2/service/s3
```

Get your AWS access keys

Access keys consist of an access key ID and secret access key, which are used to sign programmatic requests that you make to AWS. If you don't have access keys, you can create them by using the AWS Management Console. We recommend that you use IAM access keys instead of AWS root account access keys. IAM lets you securely control access to AWS services and resources in your AWS account.

> **Note**
>
> To create access keys, you must have permissions to perform the required IAM actions. For more information, see Granting IAM User Permission to Manage Password Policy and Credentials in the IAM User Guide.

To get your access key ID and secret access key.

1. Open the IAM console
2. On the navigation menu, choose **Users**.
3. Choose your IAM user name (not the check box).
4. Open the **Security credentials** tab, and then choose **Create access key**.
5. To see the new access key, choose **Show**. Your credentials resemble the following:
   - Access key ID: `AKIAIOSFODNN7EXAMPLE`
   - Secret access key: `wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY`
6. To download the key pair, choose **Download .csv file**. Store the keys in a secure location.

> **Warning**
>
> Keep the keys confidential to protect your AWS account, and never share them with anyone outside your organization.

Invoke an Operation

After you have installed the SDK, you import AWS packages into your Go applications to use the SDK, as shown in the following example, which imports the AWS, Config, and Amazon S3 libraries. After importing the SDK packages, the AWS SDK Shared Configuration is loaded, a client is constructed, and an API operation is invoked.

```
package main

import (
    "context"
    "log"
    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
)

func main() {
    // Load the Shared AWS Configuration (~/.aws/config)
    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        log.Fatal(err)
    }

    // Create an Amazon S3 service client
    client := s3.NewFromConfig(cfg)

    // Get the first page of results for ListObjectsV2 for a bucket
    output, err := client.ListObjectsV2(context.TODO(), &s3.ListObjectsV2Input{
        Bucket: aws.String("amzn-s3-demo-bucket"),
    })
    if err != nil {
        log.Fatal(err)
    }

    log.Println("first page results")
```

```
    for _, object := range output.Contents {
        log.Printf("key=%s size=%d", aws.ToString(object.Key), *object.Size)
    }
}
```

Configure the SDK

In the AWS SDK for Go V2, you can configure common settings for service clients, such as the logger, log level, and retry configuration. Most settings are optional. However, for each service client, you must specify an AWS Region and your credentials. The SDK uses these values to send requests to the correct Region and sign requests with the correct credentials. You can specify these values as programmatically in code or via the execution environment.

Loading AWS Shared Configuration Files

There are a number of ways to initialize a service API client, but the following is the most common pattern recommended to users.

To configure the SDK to use the AWS shared configuration files, use the following code:

```
import (
  "context"
  "log"
  "github.com/aws/aws-sdk-go-v2/config"
)

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
  log.Fatalf("failed to load configuration, %v", err)
}
```

`config.LoadDefaultConfig(context.TODO())` will construct an aws.Config using the AWS shared configuration sources. This includes configuring a credential provider, configuring the AWS Region, and loading service specific configuration. Service clients can be constructed using the loaded `aws.Config`, providing a consistent pattern for constructing clients.

For more information about AWS shared configuration files, see Configuration in the AWS SDKs and Tools Reference Guide.

Specifying the AWS Region

When you specify the Region, you specify where to send requests, such as `us-west-2` or `us-east-2`. For a list of Regions for each service, see Service endpoints and quotas in the Amazon Web Services General Reference.

The SDK does not have a default Region. To specify a Region:

- Set the `AWS_REGION` environment variable to the default Region.
- Set the region explicitly using config.WithRegion as an argument to `config.LoadDefaultConfig` when loading configuration.

REVIEW: If you set a Region using all of these techniques, the SDK uses the Region you explicitly specified.

Configure Region with Environment Variable

Linux, macOS, or Unix

```
export AWS_REGION=us-west-2
```

Windows

```
set AWS_REGION=us-west-2
```

Specify Region Programmatically

```
cfg, err := config.LoadDefaultConfig(context.TODO(), config.WithRegion("us-west-2"))
```

Specifying Credentials

The AWS SDK for Go requires credentials (an access key and secret access key) to sign requests to AWS. You can specify your credentials in several locations, depending on your particular use case. For information about obtaining credentials, see Get started with AWS SDK for Go.

When you initialize an `aws.Config` instance using `config.LoadDefaultConfig`, the SDK uses its default credential chain to find AWS credentials. This default credential chain looks for credentials in the following order:

1. Environment variables.
    1. Static Credentials (`AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, `AWS_SESSION_TOKEN`)
    2. Web Identity Token (`AWS_WEB_IDENTITY_TOKEN_FILE`)
2. Shared configuration files.
    1. SDK defaults to `credentials` file under `.aws` folder that is placed in the home folder on your computer.
    2. SDK defaults to `config` file under `.aws` folder that is placed in the home folder on your computer.
3. If your application uses an Amazon ECS task definition or RunTask API operation, IAM role for tasks.
4. If your application is running on an Amazon EC2 instance, IAM role for Amazon EC2.

The SDK detects and uses the built-in providers automatically, without requiring manual configurations. For example, if you use IAM roles for Amazon EC2 instances, your applications automatically use the instance's credentials. You don't need to manually configure credentials in your application.

As a best practice, AWS recommends that you specify credentials in the following order:

1. Use IAM roles for tasks if your application uses an Amazon ECS task definition or RunTask API operation.
2. Use IAM roles for Amazon EC2 (if your application is running on an Amazon EC2 instance).

   IAM roles provide applications on the instance temporary security credentials to make AWS calls. IAM roles provide an easy way to distribute and manage credentials on multiple Amazon EC2 instances.
3. Use shared credentials or config files.

   The credentials and config files are shared across other AWS SDKs and AWS CLI. As a security best practice, we recommend using credentials file for setting sensitive values such as access key IDs and secret keys. Here are the formatting requirements for each of these files.
4. Use environment variables.

   Setting environment variables is useful if you're doing development work on a machine other than an Amazon EC2 instance.

IAM Roles for Tasks

If your application uses an Amazon ECS task definition or `RunTask` operation, use IAM Roles for Tasks to specify an IAM role that can be used by the containers in a task.

IAM Roles for Amazon EC2 Instances

If you are running your application on an Amazon EC2 instance, use the instance's IAM role to get temporary security credentials to make calls to AWS.

If you have configured your instance to use IAM roles, the SDK uses these credentials for your application automatically. You don't need to manually specify these credentials.

Shared Credentials and Configuration

The shared credentials and config files can be used to share common configuration amongst AWS SDKs and other tools. If you use different credentials for different tools or applications, you can use *profiles* to configure multiple access keys in the same configuration file.

You can provide multiple credential or config files locations using `config.LoadOptions`, by default the SDK loads files stored at default locations mentioned in the Specifying Credentials.

```
import (
    "context"
    "github.com/aws/aws-sdk-go-v2/config"
)

// ...

cfg , err := config.LoadDefaultConfig(context.TODO(),
    config.WithSharedCredentialsFiles(
    []string{"test/credentials", "data/credentials"},
    ),
    config.WithSharedConfigFiles(
        []string{"test/config", "data/config"},
    )
)
```

When working with shared credentials and config files, if duplicate profiles are specified they are merged to resolve a profile. In case of merge conflict,

1. If duplicate profiles are specified within a same credentials/config file, the profile properties specified in the latter profile takes precedence.
2. If duplicate profiles are specified across either multiple credentials files or across multiple config files, the profile properties are resolved as per the order of file input to the `config.LoadOptions`. The profile properties in the latter files take precedence.
3. If a profile exists in both credentials file and config file, the credentials file properties take precedence.

If needed, you can enable `LogConfigurationWarnings` on `config.LoadOptions` and log the profile resolution steps.

Creating the Credentials File

If you don't have a shared credentials file (`.aws/credentials`), you can use any text editor to create one in your home directory. Add the following content to your credentials file, replacing *<YOUR_ACCESS_KEY_ID>* and *<YOUR_SECRET_ACCESS_KEY>* with your credentials.

```
[default]
aws_access_key_id = <YOUR_ACCESS_KEY_ID>
aws_secret_access_key = <YOUR_SECRET_ACCESS_KEY>
```

The `[default]` heading defines credentials for the default profile, which the SDK will use unless you configure it to use another profile.

You can also use temporary security credentials by adding the session tokens to your profile, as shown in the following example:

```
[temp]
aws_access_key_id = <YOUR_TEMP_ACCESS_KEY_ID>
aws_secret_access_key = <YOUR_TEMP_SECRET_ACCESS_KEY>
aws_session_token = <YOUR_SESSION_TOKEN>
```

The section name for a non-default profile within a credentials file must not begin with the word `profile`. You can read more at AWS SDKs and Tools Reference Guide.

Creating the Config File

If you don't have a shared credentials file (`.aws/config`), you can use any text editor to create one in your home directory. Add the following content to your config file, replacing *<REGION>* with the desired region.

```
[default]
region = <REGION>
```

The `[default]` heading defines config for the default profile, which the SDK will use unless you configure it to use another profile.

You can use named profiles as shown in the following example:

```
[profile named-profile]
region = <REGION>
```

The section name for a non-default profile within a config file must always begin with the word `profile`, followed by the intended profile name. You can read more at the AWS SDKs and Tools Reference Guide.

Specifying Profiles

You can include multiple access keys in the same configuration file by associating each set of access keys with a profile. For example, in your credentials file, you can declare multiple profiles, as follows.

```
[default]
aws_access_key_id = <YOUR_DEFAULT_ACCESS_KEY_ID>
aws_secret_access_key = <YOUR_DEFAULT_SECRET_ACCESS_KEY>

[test-account]
aws_access_key_id = <YOUR_TEST_ACCESS_KEY_ID>
aws_secret_access_key = <YOUR_TEST_SECRET_ACCESS_KEY>

[prod-account]
; work profile
aws_access_key_id = <YOUR_PROD_ACCESS_KEY_ID>
aws_secret_access_key = <YOUR_PROD_SECRET_ACCESS_KEY>
```

By default, the SDK checks the `AWS_PROFILE` environment variable to determine which profile to use. If no `AWS_PROFILE` variable is set, the SDK uses the `default` profile.

Sometimes, you may want to use a different profile with your application. For example, you want to use the `test-account` credentials with your `myapp` application. You can use this profile by using the following command:

```
$ AWS_PROFILE=test-account myapp
```

You can also use instruct the SDK to select a profile by either calling `os.Setenv("AWS_PROFILE", "test-account")` before calling `config.LoadDefaultConfig`, or by passing an explicit profile as an argument as shown in the following example:

```
cfg, err := config.LoadDefaultConfig(context.TODO(),
    config.WithSharedConfigProfile("test-account"))
```

> **Note**
>
> If you specify credentials in environment variables, the SDK always uses those credentials, no matter which profile you specify.

Environment Variables

By default, the SDK detects AWS credentials set in your environment and uses them to sign requests to AWS. That way you don't need to manage credentials in your applications.

The SDK looks for credentials in the following environment variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN` (optional)

The following examples show how you configure the environment variables.

Linux, OS X, or Unix

```
$ export AWS_ACCESS_KEY_ID=YOUR_AKID
```

```
$ export AWS_SECRET_ACCESS_KEY=YOUR_SECRET_KEY
$ export AWS_SESSION_TOKEN=TOKEN
```

Windows

```
> set AWS_ACCESS_KEY_ID=YOUR_AKID
> set AWS_SECRET_ACCESS_KEY=YOUR_SECRET_KEY
> set AWS_SESSION_TOKEN=TOKEN
```

Specify Credentials Programmatically

`config.LoadDefaultConfig` allows you to provide an explicit aws.CredentialProvider when loading the shared configuration sources. To pass an explicit credential provider when loading shared configuration use config.WithCredentialsProvider. For example, if `customProvider` references an instance of `aws.CredentialProvider` implementation, it can be passed during configuration loading like so:

```
cfg, err := config.LoadDefaultConfig(context.TODO(),
    config.WithCredentialsProvider(customProvider))
```

If you explicitly provide credentials, as in this example, the SDK uses only those credentials.

> **Note**
>
> All credential providers passed to or returned by `LoadDefaultConfig` are wrapped in a CredentialsCache automatically. This enables caching and credential rotation that is concurrency safe. If you explicitly configure a provider on `aws.Config` directly, you must also explicitly wrap the provider with this type using NewCredentialsCache.

Static Credentials

You can hard-code credentials in your application by using the credentials.NewStaticCredentialsProvider credential provider to explicitly set the access keys to be used. For example:

```
cfg, err := config.LoadDefaultConfig(context.TODO(),
    config.WithCredentialsProvider(credentials.NewStaticCredentialsProvider("AKID",
 "SECRET_KEY", "TOKEN")),
```

```
)
```

> **Warning**
>
> Do not embed credentials inside an application. Use this method only for testing purposes.

Single Sign-on Credentials

The SDK provides a credential provider for retrieving temporary AWS credentials using AWS IAM Identity Center. Using the AWS CLI, you authenticate with the AWS access portal and authorize access to temporary AWS credentials. You then configure your application to load the single sign-on (SSO) profile, and the SDK uses your SSO credentials to retrieve temporary AWS credentials that will be automatically renewed if expired. If your SSO credentials expire, you must explicitly renew them by logging in to your IAM Identity Center account again using the AWS CLI.

For example, you can create a profile, `dev-profile`, authenticate and authorize that profile using the AWS CLI, and configure your application as shown below.

1. First create the `profile` and `sso-session`

```
[profile dev-profile]
sso_session = dev-session
sso_account_id = 012345678901
sso_role_name = Developer
region = us-east-1

[sso-session dev-session]
sso_region = us-west-2
sso_start_url = https://company-sso-portal.awsapps.com/start
sso_registration_scopes = sso:account:access
```

2. Login using the AWS CLI to authenticate and authorize the SSO profile.

```
$ aws --profile dev-profile sso login
Attempting to automatically open the SSO authorization page in your default browser.
If the browser does not open or you wish to use a different device to authorize this
 request, open the following URL:
```

```
https://device.sso.us-west-2.amazonaws.com/

Then enter the code:

ABCD-EFGH
Successully logged into Start URL: https://company-sso-portal.awsapps.com/start
```

3. Next configure your application to use the SSO profile.

```
import "github.com/aws/aws-sdk-go-v2/config"

// ...

cfg, err := config.LoadDefaultConfig(
    context.Background(),
    config.WithSharedConfigProfile("dev-profile"),
)
if err != nil {
    return err
}
```

For more information on configuring SSO profiles and authenticating using the AWS CLI see Configuring the AWS CLI to use AWS IAM Identity Center in the AWS CLI User Guide. For more information on programmatically constructing the SSO credential provider see the ssocreds API reference documentation.

Other Credentials Providers

The SDK provides other methods for retrieving credentials in the credentials module. For example, you can retrieve temporary security credentials from AWS Security Token Service or credentials from encrypted storage.

Available Credential Providers:

- ec2rolecreds – Retrieve Credentials from Amazon EC2 Instances Roles via Amazon EC2 IMDS.
- endpointcreds – Retrieve Credentials from an arbitrary HTTP endpoint.
- processcreds – Retrieve Credentials from an external process that will be invoked by the host environment's shell.
- stscreds – Retrieve Credentials from AWS STS

Configure Authentication

The AWS SDK for Go provides the ability to configure the authentication behavior service. In most cases, the default configuration will suffice, but configuring custom authentication allows for additional behavior such as working with pre-release service features.

Definitions

This section provides a high-level description of authentication components in the AWS SDK for Go.

AuthScheme

An AuthScheme is the interface that defines the workflow through which the SDK retrieves a caller identity and attaches it to an operation request.

An auth scheme uses the following components, described in detail further below:

- A unique ID which identifies the scheme
- An identity resolver, which returns a caller identity used in the signing process (e.g. your AWS credentials)
- A signer, which performs the actual injection of caller identity into the operation's transport request (e.g. the `Authorization` HTTP header)

Each service client options includes an `AuthSchemes` field, which by default is populated with the list of auth schemes supported by that service.

AuthSchemeResolver

Each service client options includes an `AuthSchemeResolver` field. This interface, defined per-service, is the API called by the SDK to determine the possible authentication options for each operation.

> **Important**
>
> The auth scheme resolver does NOT dictate what auth scheme is used. It returns a list of schemes that *can* be used ("options"), the final scheme is selected through a fixed algorithm described here.

Option

Returned from a call to `ResolverAuthSchemes`, an Option represents a possible authentication option.

An option consists of three sets of information:

- An ID representing the possible scheme
- An opaque set of properties to be provided to the scheme's identity resolver
- An opaque set of properties to be provided to the scheme's signer

A note on properties

For 99% of use cases, callers need not be concerned with the opaque properties for identity resolution and signing. The SDK will pull out the necessary properties for each scheme and pass them to the strongly-typed interfaces exposed in the SDK. For example, the default auth resolver for services encode the SigV4 option to have signer properties for the signing name and region, the values of which are passed to the client's configured v4.HTTPSigner implementation when SigV4 is selected.

Identity

An Identity is an abstract representation of who the SDK caller is.

The most common type of identity used in the SDK is a set of `aws.Credentials`. For most use cases, the caller need not concern themselves with `Identity` as an abstraction and can work with the concrete types directly.

> **Note**
>
> To preserve backwards compatibility and prevent API confusion, the AWS SDK-specific identity type `aws.Credentials` does not directly satisfy the `Identity` interface. This mapping is handled internally.

IdentityResolver

IdentityResolver is the interface through which an `Identity` is retrieved.

Concrete versions of `IdentityResolver` exist in the SDK in strongly-typed form (e.g. aws.CredentialsProvider), the SDK handles this mapping internally.

A caller will only need to directly implement the `IdentityResolver` interface when defining an external auth scheme.

Signer

Signer is the interface through which a request is supplemented with the retrieved caller `Identity`.

Concrete versions of `Signer` exist in the SDK in strongly-typed form (e.g. v4.HTTPSigner), the SDK handles this mapping internally.

A caller will only need to directly implement the `Signer` interface when defining an external auth scheme.

AuthResolverParameters

Each service takes a specific set of inputs which are passed to its resolution function, defined in each service package as `AuthResolverParameters`.

The base resolver parameters are as follows:

name	type	description
`Operation`	`string`	The name of the operation being invoked.
`Region`	`string`	The client's AWS region. Only present for services that use SigV4[A].

If you are implementing your own resolver, you should never need to construct your own instance of its parameters. The SDK will source these values per-request and pass them to your implementation.

Auth scheme resolution workflow

When you call an AWS service operation through the SDK, the following sequence of actions occurs after the request has been serialized:

1. The SDK calls the client's `AuthSchemeResolver.ResolveAuthSchemes()` API, sourcing the input parameters as necessary, to obtain a list of possible Options for the operation.
2. The SDK iterates over that list and selects the first scheme that satisfies the following conditions.
   - A scheme with matching ID is present in the client's own `AuthSchemes` list
   - The scheme's identity resolver exists (is non-`nil`) on the client's Options (checked via the scheme's `GetIdentityResolver` method, the mapping to the concrete identity resolver types described above is handled internally) (1)
3. Assuming a viable scheme was selected, the SDK invokes its `GetIdentityResolver()` API to retrieve the caller's identity. For example, the builtin SigV4 auth scheme will map to the client's `Credentials` provider internally.
4. The SDK calls the identity resolver's `GetIdentity()` (e.g. `aws.CredentialProvider.Retrieve()` for SigV4).
5. The SDK calls the endpoint resolver's `ResolveEndpoint()` to find the endpoint for the request. The endpoint may include additional metadata that influences the signing process (e.g. unique signing name for S3 Object Lambda).
6. The SDK calls the auth scheme's `Signer()` API to retrieve its signer, and uses its `SignRequest()` API to sign the request with the previously-retrieved caller identity.

(1) If the SDK encounters the anonymous option (ID `smithy.api#noAuth`) in the list, it is selected automatically, as there is no corresponding identity resolver.

Natively-supported `AuthSchemes`

The following auth schemes are natively supported by AWS SDK for Go.

Name	Scheme ID	Identity resolver	Signer	Notes
SigV4	`aws.auth#sigv4`	aws.CredentialsProvider	v4.HTTPSigner	The current default for most

Name	Scheme ID	Identity resolver	Signer	Notes
				AWS service operations.
SigV4A	`aws.auth#sigv4a`	aws.CredentialsProvider	n/a	SigV4A usage is limited at this time, the signer implementation is internal. See this announcement for a new opt-in module *aws-http-auth* that exposes general purpose APIs for signing HTTP requests.
SigV4Express	`com.amazonaws.s3#sigv4express`	s3.ExpressCredentialsProvider	v4.HTTPSigner	Used for Express One Zone.
HTTP Bearer	`smithy.api#httpBearerAuth`	smithybearer.TokenProvider	smithybearer.Signer	Used by codecatalyst.
Anonymous	`smithy.api#noAuth`	n/a	n/a	No authentication - no identity is required, and the request is not signed or authenticated.

Identity configuration

In AWS SDK for Go, the identity components of an auth scheme are configured in SDK client `Options`. The SDK will automatically pick up and use the values for these components for the scheme it selects when an operation is called.

> **Note**
>
> For backwards compatibility reasons, the SDK implicitly allows the use of the anonymous auth scheme if no identity resolvers are configured. This can be manually achieved by setting all identity resolvers on a client's `Options` to `nil` (the sigv4 identity resolver can also be set to `aws.AnonymousCredentials{}`).

Signer configuration

In AWS SDK for Go, the signer components of an auth scheme are configured in SDK client `Options`. The SDK will automatically pick up and use the values for these components for the scheme it selects when an operation is called. No additional configuration is necessary.

Custom auth scheme

In order to define a custom auth scheme and configure it for use, the caller must do the following:

1. Define an AuthScheme implementation
2. Register the scheme on the SDK client's `AuthSchemes` list
3. Instrument the SDK client's `AuthSchemeResolver` to return an auth `Option` with the scheme's ID where applicable

> **Warning**
>
> The following services have unique or customized authentication behavior. We recommend you delegate to the default implementation and wrap accordingly if you require custom authentication behavior:

Service	Notes
S3	Conditional use of SigV4A and SigV4Express depending on operation input.
EventBridge	Conditional use of SigV4A depending on operation input.
Cognito	Certain operations are anonymous-only.
SSO	Certain operations are anonymous-only.
STS	Certain operations are anonymous-only.

Configure Client Endpoints

Warning

Endpoint resolution is an advanced SDK topic. By changing these settings you risk breaking your code. The default settings should be applicable to most users in production environments.

The AWS SDK for Go provides the ability to configure a custom endpoint to be used for a service. In most cases, the default configuration will suffice. Configuring custom endpoints allows for additional behavior, such as working with pre-release versions of a service.

Customization

There are two "versions" of endpoint resolution config within the SDK.

- v2, released in Q3 of 2023, configured via:
  - `EndpointResolverV2`
  - `BaseEndpoint`
- v1, released alongside the SDK, configured via:
  - `EndpointResolver`

We recommend users of v1 endpoint resolution migrate to v2 to obtain access to newer endpoint-related service features.

V2: `EndpointResolverV2` + `BaseEndpoint`

In resolution v2, `EndpointResolverV2` is the definitive mechanism through which endpoint resolution occurs. The resolver's `ResolveEndpoint` method is invoked as part of the workflow for every request you make in the SDK. The hostname of the `Endpoint` returned by the resolver is used **as-is** when making the request (operation serializers can still append to the HTTP path, however).

Resolution v2 includes an additional client-level config, `BaseEndpoint`, which is used to specify a "base" hostname for the instance of your service. The value set here is not definitive-- it is ultimately passed as a parameter to the client's `EndpointResolverV2` when final resolution occurs (read on for more information about `EndpointResolverV2` parameters). The resolver implementation then has the opportunity to inspect and potentially modify that value to determine the final endpoint.

For example, if you perform an S3 `GetObject` request against a given bucket with a client where you've specified a `BaseEndpoint`, the default resolver will inject the bucket into the hostname if it is virtual-host compatible (assuming you haven't disabled virtual-hosting in client config).

In practice, `BaseEndpoint` will most likely be used to point your client at a development or preview instance of a service.

`EndpointResolverV2` parameters

Each service takes a specific set of inputs which are passed to its resolution function, defined in each service package as `EndpointParameters`.

Every service includes the following base parameters, which are used to facilitate general endpoint resolution within AWS:

name	type	description
`Region`	`string`	The client's AWS region
`Endpoint`	`string`	The value set for `BaseEndpoint` in client config

name	type	description
`UseFips`	`bool`	Whether FIPS endpoints are enabled in client config
`UseDualStack`	`bool`	Whether dual-stack endpoints are enabled in client config

Services can specify additional parameters required for resolution. For example, S3's `EndpointParameters` include the bucket name, as well as several S3-specific feature settings such as whether virtual host addressing is enabled.

If you are implementing your own `EndpointResolverV2`, you should never need to construct your own instance of `EndpointParameters`. The SDK will source the values per-request and pass them to your implementation.

A note about Amazon S3

Amazon S3 is a complex service with many of its features modeled through complex endpoint customizations, such as bucket virtual hosting, S3 MRAP, and more.

Because of this, we recommend that you don't replace the `EndpointResolverV2` implementation in your S3 client. If you need to extend its resolution behavior, perhaps by sending requests to a local development stack with additional endpoint considerations, we recommend wrapping the default implementation such that it delegates back to the default as a fallback (shown in examples below).

Examples

With `BaseEndpoint`

The following code snippet shows how to point your S3 client at a local instance of a service, which in this example is hosted on the loopback device at port 8080.

```
client := s3.NewFromConfig(cfg, func (o *svc.Options) {
    o.BaseEndpoint = aws.String("https://localhost:8080/")
})
```

With `EndpointResolverV2`

The following code snippet shows how to inject custom behavior into S3's endpoint resolution using `EndpointResolverV2`.

```
import (
    "context"
    "net/url"

    "github.com/aws/aws-sdk-go-v2/service/s3"
    smithyendpoints "github.com/aws/smithy-go/endpoints"
)

type resolverV2 struct {
    // you could inject additional application context here as well
}

func (*resolverV2) ResolveEndpoint(ctx context.Context, params s3.EndpointParameters) (
        smithyendpoints.Endpoint, error,
    ) {
    if /* input params or caller context indicate we must route somewhere */ {
        u, err := url.Parse("https://custom.service.endpoint/")
        if err != nil {
            return smithyendpoints.Endpoint{}, err
        }
        return smithyendpoints.Endpoint{
            URI: *u,
        }, nil
    }

    // delegate back to the default v2 resolver otherwise
    return s3.NewDefaultEndpointResolverV2().ResolveEndpoint(ctx, params)
}

func main() {
    // load config...

    client := s3.NewFromConfig(cfg, func (o *s3.Options) {
        o.EndpointResolverV2 = &resolverV2{
            // ...
        }
    })
}
```

With both

The following sample program demonstrates the interaction between `BaseEndpoint` and `EndpointResolverV2`. **This is an advanced use case:**

```
import (
    "context"
    "fmt"
    "log"
    "net/url"

    "github.com/aws/aws-sdk-go-v2"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
    smithyendpoints "github.com/aws/smithy-go/endpoints"
)

type resolverV2 struct {}

func (*resolverV2) ResolveEndpoint(ctx context.Context, params s3.EndpointParameters) (
        smithyendpoints.Endpoint, error,
    ) {
    // s3.Options.BaseEndpoint is accessible here:
    fmt.Printf("The endpoint provided in config is %s\n", *params.Endpoint)

    // fallback to default
    return s3.NewDefaultEndpointResolverV2().ResolveEndpoint(ctx, params)
}

func main() {
    cfg, err := config.LoadDefaultConfig(context.Background())
    if (err != nil) {
        log.Fatal(err)
    }

    client := s3.NewFromConfig(cfg, func (o *s3.Options) {
        o.BaseEndpoint = aws.String("https://endpoint.dev/")
        o.EndpointResolverV2 = &resolverV2{}
    })

    // ignore the output, this is just for demonstration
    client.ListBuckets(context.Background(), nil)
}
```

When run, the above program outputs the following:

```
The endpoint provided in config is https://endpoint.dev/
```

V1: EndpointResolver

> **Warning**
>
> Endpoint resolution v1 is retained for backwards compatibility and is isolated from the modern behavior in endpoint resolution v2. It will only be used if the `EndpointResolver` field is set by the caller.
> Use of v1 will most likely prevent you from accessing endpoint-related service features introduced with or after the release of v2 resolution. See "Migration" for instructions on how to upgrade.

A EndpointResolver can be configured to provide custom endpoint resolution logic for service clients. You can use a custom endpoint resolver to override a service's endpoint resolution logic for all endpoints, or a just specific regional endpoint. Custom endpoint resolver can trigger the service's endpoint resolution logic to fallback if a custom resolver does not wish to resolve a requested endpoint. EndpointResolverWithOptionsFunc can be used to easily wrap functions to satisfy the `EndpointResolverWithOptions` interface.

A `EndpointResolver` can be easily configured by passing the resolver wrapped with WithEndpointResolverWithOptions to LoadDefaultConfig , allowing for the ability to override endpoints when loading credentials, as well as configuring the resulting `aws.Config` with your custom endpoint resolver.

The endpoint resolver is given the service and region as a string, allowing for the resolver to dynamically drive its behavior. Each service client package has an exported `ServiceID` constant which can be used to determine which service client is invoking your endpoint resolver.

An endpoint resolver can use the EndpointNotFoundError sentinel error value to trigger fallback resolution to the service clients default resolution logic. This allows you to selectively override one or more endpoints seamlessly without having to handle fallback logic.

If your endpoint resolver implementation returns an error other than `EndpointNotFoundError`, endpoint resolution will stop and the service operation returns an error to your application.

Examples

With fallback

The following code snippet shows how a single service endpoint can be overridden for DynamoDB with fallback behavior for other endpoints:

```
customResolver := aws.EndpointResolverWithOptionsFunc(func(service, region string,
 options ...interface{}) (aws.Endpoint, error) {
    if service == dynamodb.ServiceID && region == "us-west-2" {
        return aws.Endpoint{
            PartitionID:   "aws",
            URL:           "https://test.us-west-2.amazonaws.com",
            SigningRegion: "us-west-2",
        }, nil
    }
    // returning EndpointNotFoundError will allow the service to fallback to it's
 default resolution
    return aws.Endpoint{}, &aws.EndpointNotFoundError{}
})

cfg, err := config.LoadDefaultConfig(context.TODO(),
 config.WithEndpointResolverWithOptions(customResolver))
```

Without fallback

The following code snippet shows how a single service endpoint can be overridden for DynamoDB without fallback behavior for other endpoints:

```
customResolver := aws.EndpointResolverWithOptionsFunc(func(service, region string,
 options ...interface{}) (aws.Endpoint, error) {
    if service == dynamodb.ServiceID && region == "us-west-2" {
        return aws.Endpoint{
            PartitionID:   "aws",
            URL:           "https://test.us-west-2.amazonaws.com",
            SigningRegion: "us-west-2",
        }, nil
    }
    return aws.Endpoint{}, fmt.Errorf("unknown endpoint requested")
})
```

```
cfg, err := config.LoadDefaultConfig(context.TODO(),
 config.WithEndpointResolverWithOptions(customResolver))
```

Immutable endpoints

> **Warning**
>
> Setting an endpoint as immutable may prevent some service client features from functioning correctly, and could result in undefined behavior. Caution should be taken when defining an endpoint as immutable.

Some service clients, such as Amazon S3, may modify the endpoint returned by the resolver for certain service operations. For example, Amazon S3 will automatically handle Virtual Bucket Addressing by mutating the resolved endpoint. You can prevent the SDK from mutating your custom endpoints by setting HostnameImmutable to `true`. For example:

```
customResolver := aws.EndpointResolverWithOptionsFunc(func(service, region string,
 options ...interface{}) (aws.Endpoint, error) {
    if service == dynamodb.ServiceID && region == "us-west-2" {
        return aws.Endpoint{
            PartitionID:   "aws",
            URL:           "https://test.us-west-2.amazonaws.com",
            SigningRegion: "us-west-2",
            HostnameImmutable: true,
        }, nil
    }
    return aws.Endpoint{}, fmt.Errorf("unknown endpoint requested")
})

cfg, err := config.LoadDefaultConfig(context.TODO(),
 config.WithEndpointResolverWithOptions(customResolver))
```

Migration

When migrating from v1 to v2 of endpoint resolution, the following general principles apply:

- Returning an Endpoint with HostnameImmutable set to `false` is roughly equivalent to setting `BaseEndpoint` to the originally returned URL from v1 and leaving `EndpointResolverV2` as the default.

- Returning an Endpoint with HostnameImmutable set to `true` is roughly equivalent to implementing an `EndpointResolverV2` which returns the originally returned URL from v1.
  - The primary exception is for operations with modeled endpoint prefixes. A note on this is given further down.

Examples for these cases are provided below.

> **Warning**
>
> V1 immutable endpoints and V2 resolution are not equivalent in behavior. For example, signing overrides for custom features like S3 Object Lambda would still be set for immutable endpoints returned via v1 code, but the same will not be done for v2.

Note on host prefixes

Some operations are modeled with host prefixes to be prepended to the resolved endpoint. This behavior must work in tandem with the output of ResolveEndpointV2 and therefore the host prefix will still be applied to that result.

You can manually disable endpoint host prefixing by applying a middleware, see the examples section.

Examples

Mutable endpoint

The following code sample demonstrates how to migrate a basic v1 endpoint resolver that returns a modifiable endpoint:

```
// v1
client := svc.NewFromConfig(cfg, func (o *svc.Options) {
    o.EndpointResolver = svc.EndpointResolverFromURL("https://custom.endpoint.api/")
})

// v2
client := svc.NewFromConfig(cfg, func (o *svc.Options) {
    // the value of BaseEndpoint is passed to the default EndpointResolverV2
    // implementation, which will handle routing for features such as S3 accelerate,
    // MRAP, etc.
    o.BaseEndpoint = aws.String("https://custom.endpoint.api/")
```

```
})
```

Immutable endpoint

```
// v1
client := svc.NewFromConfig(cfg, func (o *svc.Options) {
    o.EndpointResolver = svc.EndpointResolverFromURL("https://custom.endpoint.api/",
 func (e *aws.Endpoint) {
        e.HostnameImmutable = true
    })
})

// v2
import (
    smithyendpoints "github.com/aws/smithy-go/endpoints"
)

type staticResolver struct {}

func (*staticResolver) ResolveEndpoint(ctx context.Context, params
 svc.EndpointParameters) (
        smithyendpoints.Endpoint, error,
    ) {
    // This value will be used as-is when making the request.
    u, err := url.Parse("https://custom.endpoint.api/")
    if err != nil {
        return smithyendpoints.Endpoint{}, err
    }
    return smithyendpoints.Endpoint{
        URI: *u,
    }, nil
}

client := svc.NewFromConfig(cfg, func (o *svc.Options) {
    o.EndpointResolverV2 = &staticResolver{}
})
```

Disable host prefix

```
import (
    "context"
    "fmt"
    "net/url"
```

```
    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/<service>"
    smithyendpoints "github.com/aws/smithy-go/endpoints"
    "github.com/aws/smithy-go/middleware"
    smithyhttp "github.com/aws/smithy-go/transport/http"
)

// disableEndpointPrefix applies the flag that will prevent any
// operation-specific host prefix from being applied
type disableEndpointPrefix struct{}

func (disableEndpointPrefix) ID() string { return "disableEndpointPrefix" }

func (disableEndpointPrefix) HandleInitialize(
    ctx context.Context, in middleware.InitializeInput, next
 middleware.InitializeHandler,
) (middleware.InitializeOutput, middleware.Metadata, error) {
    ctx = smithyhttp.SetHostnameImmutable(ctx, true)
    return next.HandleInitialize(ctx, in)
}

func addDisableEndpointPrefix(o *<service>.Options) {
    o.APIOptions = append(o.APIOptions, (func(stack *middleware.Stack) error {
        return stack.Initialize.Add(disableEndpointPrefix{}, middleware.After)
    }))
}

type staticResolver struct{}

func (staticResolver) ResolveEndpoint(ctx context.Context, params
 <service>.EndpointParameters) (
    smithyendpoints.Endpoint, error,
) {
    u, err := url.Parse("https://custom.endpoint.api/")
    if err != nil {
        return smithyendpoints.Endpoint{}, err
    }

    return smithyendpoints.Endpoint{URI: *u}, nil
}
```

```
func main() {
    cfg, err := config.LoadDefaultConfig(context.Background())
    if err != nil {
        panic(err)
    }

    svc := <service>.NewFromConfig(cfg, func(o *<service>.Options) {
        o.EndpointResolverV2 = staticResolver{}
    })

    _, err = svc.<Operation>(context.Background(), &<service>.<OperationInput>{ /* ...
 */ },
        addDisableEndpointPrefix)
    if err != nil {
        panic(err)
    }
}
```

Customize the HTTP Client

The AWS SDK for Go uses a default HTTP client with default configuration values. Although you can change some of these configuration values, the default HTTP client and transport are not sufficiently configured for customers using the AWS SDK for Go in an environment with high throughput and low latency requirements. For more information, please refer to the Frequently Asked Questions as configuration recommendations vary based on specific workloads. This section describes how to configure a custom HTTP client, and use that client to create AWS SDK for Go calls.

To assist you in creating a custom HTTP client, this section describes how to the NewBuildableClient to configure custom settings, and use that client with an AWS SDK for Go service client.

Let's define what we want to customize.

Overriding During Configuration Loading

Custom HTTP clients can be provided when calling LoadDefaultConfig by wrapping the client using WithHTTPClient and passing the resulting value to `LoadDefaultConfig`. For example, to pass `customClient` as our client:

```
cfg, err := config.LoadDefaultConfig(context.TODO(),
 config.WithHTTPClient(customClient))
```

Timeout

The `BuildableHTTPClient` can be configured with a request timeout limit. This timeout includes the time to connect, process any redirects, and read the complete response body. For example, to modify the client timeout:

```
import "github.com/aws/aws-sdk-go-v2/aws/transport/http"

// ...

httpClient := http.NewBuildableClient().WithTimeout(time.Second*5)
```

Dialer

The `BuildableHTTPClient` provides a builder mechanics for constructing clients with modified Dialer options. The following example shows how to configure a clients `Dialer` settings.

```
import awshttp "github.com/aws/aws-sdk-go-v2/aws/transport/http"
import "net"

// ...

httpClient := awshttp.NewBuildableClient().WithDialerOptions(func(d *net.Dialer) {
    d.KeepAlive = -1
    d.Timeout = time.Millisecond*500
})
```

Settings

Dialer.KeepAlive

This setting represents the keep-alive period for an active network connection.

Set to a negative value to disable keep-alives.

Set to **0** to enable keep-alives if supported by the protocol and operating system.

Network protocols or operating systems that do not support keep-alives ignore this field. By default, TCP enables keep alive.

See https://golang.org/pkg/net/#Dialer.KeepAlive

Set `KeepAlive` as **time.Duration**.

Dialer.Timeout

This setting represents the maximum amount of time a dial waits for a connection to be created.

Default is 30 seconds.

See https://golang.org/pkg/net/#Dialer.Timeout

Set `Timeout` as **time.Duration**.

Transport

The `BuildableHTTPClient` provides a builder mechanics for constructing clients with modified Transport options.

Configuring a Proxy

If you cannot directly connect to the internet, you can use Go-supported environment variables (`HTTP_PROXY`/`HTTPS_PROXY`) or create a custom HTTP client to configure your proxy. The following example configures the client to use `PROXY_URL` as the proxy endpoint:

```
import awshttp "github.com/aws/aws-sdk-go-v2/aws/transport/http"
import "net/http"

// ...

httpClient := awshttp.NewBuildableClient().WithTransportOptions(func(tr
 *http.Transport) {
    proxyURL, err := url.Parse("PROXY_URL")
    if err != nil {
        log.Fatal(err)
    }
    tr.Proxy = http.ProxyURL(proxyURL)
})
```

Other Settings

Below are a few other `Transport` settings that can be modified to tune the HTTP client. Any additional settings not described here can be found in the Transport type documentation. These settings can be applied as shown in the following example:

```
import awshttp "github.com/aws/aws-sdk-go-v2/aws/transport/http"
import "net/http"

// ...

httpClient := awshttp.NewBuildableClient().WithTransportOptions(func(tr
 *http.Transport) {
    tr.ExpectContinueTimeout = 0
    tr.MaxIdleConns = 10
})
```

Transport.ExpectContinueTimeout

If the request has an "Expect: 100-continue" header, this setting represents the maximum amount of time to wait for a server's first response headers after fully writing the request headers, This time does not include the time to send the request header. The HTTP client sends its payload after this timeout is exhausted.

Default 1 second.

Set to **0** for no timeout and send request payload without waiting. One use case is when you run into issues with proxies or third party services that take a session similar to the use of Amazon S3 in the function shown later.

See https://golang.org/pkg/net/http/#Transport.ExpectContinueTimeout

Set `ExpectContinue` as **time.Duration**.

Transport.IdleConnTimeout

This setting represents the maximum amount of time to keep an idle network connection alive between HTTP requests.

Set to **0** for no limit.

See https://golang.org/pkg/net/http/#Transport.IdleConnTimeout

Set `IdleConnTimeout` as **time.Duration**.

Transport.MaxIdleConns

This setting represents the maximum number of idle (keep-alive) connections across all hosts. One use case for increasing this value is when you are seeing many connections in a short period from the same clients

0 means no limit.

See https://golang.org/pkg/net/http/#Transport.MaxIdleConns

Set`MaxIdleConns` as **int**.

Transport.MaxIdleConnsPerHost

This setting represents the maximum number of idle (keep-alive) connections to keep per-host. One use case for increasing this value is when you are seeing many connections in a short period from the same clients

Default is two idle connections per host.

Set to **0** to use DefaultMaxIdleConnsPerHost (2).

See https://golang.org/pkg/net/http/#Transport.MaxIdleConnsPerHost

Set `MaxIdleConnsPerHost` as **int**.

Transport.ResponseHeaderTimeout

This setting represents the maximum amount of time to wait for a client to read the response header.

If the client isn't able to read the response's header within this duration, the request fails with a timeout error.

Be careful setting this value when using long-running Lambda functions, as the operation does not return any response headers until the Lambda function has finished or timed out. However, you can still use this option with the ** InvokeAsync** API operation.

Default is no timeout; wait forever.

See https://golang.org/pkg/net/http/#Transport.ResponseHeaderTimeout

Set `ResponseHeaderTimeout` as **time.Duration**.

Transport.TLSHandshakeTimeout

This setting represents the maximum amount of time waiting for a TLS handshake to be completed.

Default is 10 seconds.

Zero means no timeout.

See https://golang.org/pkg/net/http/#Transport.TLSHandshakeTimeout

Set `TLSHandshakeTimeout` as **time.Duration**.

HTTP Interceptors

You can use interceptors to hook into the execution of API requests and responses. Interceptors are open-ended mechanisms in which the SDK calls code that you write to inject behavior into the request/response lifecycle. This way, you can modify an in-flight request, debug request processing, view exceptions, and more.

Interceptors vs. middleware

The AWS SDK for Go v2 provides both interceptors and middleware for customizing request processing. While both serve similar purposes, they are designed for different audiences and use cases:

- **Interceptors** are designed for SDK users who want to customize request/response processing with a simple, HTTP-focused API. They provide specific hook points in the request lifecycle and work directly with HTTP requests and responses.
- **Middleware** is a more advanced, transport-agnostic system primarily used internally by the SDK. While powerful, middleware requires deeper knowledge of SDK internals and involves more complex interfaces.

Key advantages of interceptors over middleware for common use cases:

- **HTTP-focused**: Interceptors work directly with HTTP requests and responses, eliminating the need for transport type checking that middleware requires.

- **Simpler interfaces**: Each interceptor hook has a specific, focused interface rather than the generic middleware pattern.
- **Clearer execution model**: Interceptors execute at well-defined points in the request lifecycle without requiring knowledge of middleware stack ordering.

> **Note**
>
> Interceptors are built on top of the existing middleware system, so both can coexist in the same application. Middleware remains available for advanced use cases that require transport-agnostic behavior or complex stack manipulation.

Available interceptor hooks

The AWS SDK for Go v2 provides interceptor hooks at various stages of the request lifecycle. Each hook corresponds to a specific interface that you can implement:

- `BeforeExecution` - First hook called during operation execution
- `BeforeSerialization` - Before input message is serialized into transport request
- `AfterSerialization` - After input message is serialized into transport request
- `BeforeRetryLoop` - Before entering the retry loop
- `BeforeAttempt` - First hook called inside retry loop
- `BeforeSigning` - Before transport request is signed
- `AfterSigning` - After transport request is signed
- `BeforeTransmit` - Before transport request is sent
- `AfterTransmit` - After receiving transport response
- `BeforeDeserialization` - Before transport response is deserialized
- `AfterDeserialization` - After unmarshalling transport response
- `AfterAttempt` - Last hook called inside retry loop
- `AfterExecution` - Last hook called during operation execution

You can implement multiple interfaces in a single interceptor to hook into multiple stages of the request lifecycle.

Interceptor registration

You register interceptors when you construct a service client or when you override configuration for a specific operation. The registration differs depending on whether you want the interceptor to apply to all operations for your client or only specific ones.

Interceptors are managed through an interceptor registry that provides methods to add and remove interceptors. The following example shows a simple interceptor that adds an AWS X-Ray trace ID header to outgoing requests before the signing process:

```
type recursionDetection struct{}

func (recursionDetection) BeforeSigning(ctx context.Context, in
 *smithyhttp.InterceptorContext) error {
    if traceID := os.Getenv("_X_AMZN_TRACE_ID"); traceID != "" {
        in.Request.Header.Set("X-Amzn-Trace-Id", traceID)
    }
    return nil
}

// use it on the client
svc := s3.NewFromConfig(cfg, func(o *s3.Options) {
    o.Interceptors.AddBeforeSigning(recursionDetection{})
})
```

The interceptor registry is added to client Options, which enables per-operation interceptor configuration:

```
// ... or use it per-operation
s3.ListBuckets(context.Background(), &s3.ListBucketsInput{
}, func(o *s3.Options) {
   o.Interceptors.AddBeforeSigning(recursionDetection{})
})
```

Global interceptor configuration

You can also register interceptors globally using the `config.LoadDefaultConfig` function with the appropriate `With*` options for each interceptor type. This applies the interceptor to all AWS service clients created from that configuration:

```
type myExecutionInterceptor struct{}
```

```
func (*myExecutionInterceptor) AfterExecution(ctx context.Context, in
 *smithyhttp.InterceptorContext) error {
    // Add your custom logic here
    return nil
}

cfg, err := config.LoadDefaultConfig(context.Background(),
    config.WithAfterExecution(&myExecutionInterceptor{}))
if err != nil {
    panic(err)
}

// every service client created from the above config
// will include this interceptor
svc := s3.NewFromConfig(cfg)
```

Logging

The AWS SDK for Go has logging facilities available that allow your application to enable debugging information for debugging and diagnosing request issues or failures. The Logger interface and ClientLogMode are the main components available to you for determining how and what should be logged by clients.

Logger

When constructing an Config using LoadDefaultConfig a default `Logger` is configured to send log messages to the process' standard error (stderr). A custom logger that satisfies the Logger interface can be passed as an argument to `LoadDefaultConfig` by wrapping it with config.WithLogger.

For example, to configure our clients to use our `applicationLogger`:

```
cfg, err := config.LoadDefaultConfig(context.TODO(),
 config.WithLogger(applicationLogger))
```

Now clients configured using the constructed `aws.Config` will send log messages to `applicationLogger`.

Context-Aware Loggers

A Logger implementation may implement the optional ContextLogger interface. Loggers that implement this interface will have their `WithContext` methods invoked with the current context. This allows your logging implementations to return a new `Logger` that can write additional logging metadata based on values present in the context.

ClientLogMode

By default, service clients do not produce log messages. To configure clients to send log messages for debugging purposes, use the ClientLogMode member on `Config`. `ClientLogMode` can be set to enable debugging messaging for:

- Signature Version 4 (SigV4) Signing
- Request Retries
- HTTP Requests
- HTTP Responses

For example, to enable logging of HTTP requests and retries:

```
cfg, err := config.LoadDefaultConfig(context.TODO(),
 config.WithClientLogMode(aws.LogRetries | aws.LogRequest))
```

See ClientLogMode for the different client log modes available.

Retries and Timeouts

The AWS SDK for Go enables you to configure the retry behavior of requests to HTTP services. By default, service clients use retry.Standard as their default retryer. If the default configuration or behavior does not meet your application requirements, you can adjust the retryer configuration or provide your own retryer implementation.

The AWS SDK for Go provides a aws.Retryer interface that defines the set of methods required by a retry implementation to implement. The SDK provides two implementations for retries: retry.Standard and aws.NoOpRetryer.

Standard Retryer

The retry.Standard retryer is the default `aws.Retryer` implementation used by SDK clients. The standard retryer is a rate limited retryer with a configurable number of max attempts, and the ability to tune the request back off policy.

The following table defines the default values for this retryer:

Property	Default
Max Number of Attempts	3
Max Back Off Delay	20 seconds

When a retryable error occurs while invoking your request, the standard retryer will use its provided configuration to delay and subsequently retry the request. Retries add to the overall latency of your request, and you must configure retryer if the default configuration does not meet your application requirements.

See the retry package documentation for details on what errors are considered as retryable by the standard retryer implementation.

NopRetryer

The aws.NopRetryer is a `aws.Retryer` implementation that is provided if you wish to disable all retry attempts. When invoking a service client operation, this retryer will only allow the request to be attempted once, and any resulting error will be returned to the calling application.

Customizing Behavior

The SDK provides a set of helper utilities that wrap an `aws.Retryer` implementation, and returns the provided retryer wrapped with the desired retry behavior. You can override the default retryer for all clients, per client, or per operation depending on your applications requirements. To see additional examples showing how to do this, see the retry package documentation examples.

> **Warning**
>
> If specifying a global `aws.Retryer` implementation using `config.WithRetryer`, you must ensure that you return a new instance of the `aws.Retryer` each invocation. This will ensure that you won't create a global retry token bucket across all service clients.

Limiting the max number of attempts

You use retry.AddWithMaxAttempts to wrap an `aws.Retryer` implementation to set the max number attempts to your desired value. Setting max attempts to zero will allow the SDK to retry all retryable errors until the request succeeds, or a non-retryable error is returned.

For example, you can the following code to wrap the standard client retryer with a maximum of five attempts:

```
import "context"
import "github.com/aws/aws-sdk-go-v2/aws/retry"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO(), config.WithRetryer(func()
 aws.Retryer {
    return retry.AddWithMaxAttempts(retry.NewStandard(), 5)
}))
if err != nil {
    return err
}

client := s3.NewFromConfig(cfg)
```

Limiting the max back off delay

You use retry.AddWithMaxBackoffDelay to wrap an `aws.Retryer` implementation and limit the max back off delay that is allowed to occur between retrying a failed request.

For example, you can the following code to wrap the standard client retryer with a desired max delay of five seconds:

```
import "context"
import "time"
import "github.com/aws/aws-sdk-go-v2/aws/retry"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO(), config.WithRetryer(func()
 aws.Retryer {
    return retry.AddWithMaxBackoffDelay(retry.NewStandard(), time.Second*5)
}))
if err != nil {
    return err
}

client := s3.NewFromConfig(cfg)
```

Retry additional API error codes

You use retry.AddWithErrorCodes to wrap an `aws.Retryer` implementation and include additional API error codes that should be considered retryable.

For example, you can the following code to wrap the standard client retryer to include the Amazon S3 `NoSuchBucketException` exception as retryable.

```
import "context"
import "time"
import "github.com/aws/aws-sdk-go-v2/aws/retry"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"
import "github.com/aws/aws-sdk-go-v2/service/s3/types"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO(), config.WithRetryer(func()
 aws.Retryer {
    return retry.AddWithErrorCodes(retry.NewStandard(), (*types.NoSuchBucketException)
(nil).ErrorCode())
}))
if err != nil {
    return err
```

```
}

client := s3.NewFromConfig(cfg)
```

Client-side rate limiting

The AWS SDK for Go introduces a new client-side rate-limiting mechanism in the standard retry policy to align with the behavior of modern SDKs. This is behavior is controlled by the RateLimiter field on a retryer's options.

A RateLimiter operates as a token bucket with a set capacity, where operation attempt failures consume tokens. A retry that attempts to consume more tokens than what's available results in operation failure with a QuotaExceededError.

The default implementation is parameterized as follows (how to modify each setting):

- a capacity of 500 (set the value of RateLimiter on StandardOptions using NewTokenRateLimit)
- a retry caused by a timeout costs 10 tokens (set RetryTimeoutCost on StandardOptions)
- a retry caused by other errors costs 5 tokens (set RetryCost on StandardOptions)
- an operation that succeeds on the 1st attempt adds 1 token (set NoRetryIncrement on StandardOptions)
  - operations that succeed on the 2nd or later attempt do not add back any tokens

If you find that the default behavior does not fit your application's needs, you can disable it with ratelimit.None.

Example: modified rate limiter

```
import (
    "context"

    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/aws/ratelimit"
    "github.com/aws/aws-sdk-go-v2/aws/retry"
    "github.com/aws/aws-sdk-go-v2/config"
)

// ...

cfg, err := config.LoadDefaultConfig(context.Background(), config.WithRetryer(func()
 aws.Retryer {
```

```
    return retry.NewStandard(func(o *retry.StandardOptions) {
        // Makes the rate limiter more permissive in general. These values are
        // arbitrary for demonstration and may not suit your specific
        // application's needs.
        o.RateLimiter = ratelimit.NewTokenRateLimit(1000)
        o.RetryCost = 1
        o.RetryTimeoutCost = 3
        o.NoRetryIncrement = 10
    })
}))
```

Example: no rate limit using ratelimit.None

```
import (
    "context"

    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/aws/ratelimit"
    "github.com/aws/aws-sdk-go-v2/aws/retry"
    "github.com/aws/aws-sdk-go-v2/config"
)

// ...

cfg, err := config.LoadDefaultConfig(context.Background(), config.WithRetryer(func()
 aws.Retryer {
    return retry.NewStandard(func(o *retry.StandardOptions) {
        o.RateLimiter = ratelimit.None
    })
}))
```

Timeouts

You use the context package to set timeouts or deadlines when invoking a service client operation. Use the context.WithDeadline to wrap your applications context and set a deadline to a specific time by which the invoked operation must be completed. To set a timeout after a certain `time.Duration` use context.WithTimeout. The SDK passes the provided `context.Context` to the HTTP transport client when invoking a service API. If the context passed to the SDK is cancelled or becomes cancelled while invoking the operation, the SDK will not retry the request further and will return to the calling application. You must handle context cancellation appropriately in your application in cases where the context provided to the SDK has become cancelled.

Setting a timeout

The following example shows how to set a timeout for a service client operation.

```
import "context"
import "time"

// ...

ctx := context.TODO() // or appropriate context.Context value for your application

client := s3.NewFromConfig(cfg)

// create a new context from the previous ctx with a timeout, e.g. 5 seconds
ctx, cancel := context.WithTimeout(ctx, 5*time.Second)
defer cancel()

resp, err := client.GetObject(ctx, &s3.GetObjectInput{
    // input parameters
})
if err != nil {
    // handle error
}
```

Using the AWS SDK for Go

Learn common and recommended ways of programming with the AWS SDK for Go in your applications.

Topics

Constructing a Service Client

Service clients can be constructed using either the `New` or `NewFromConfig` functions available in service client's Go package. Each function will return a `Client` struct type containing the methods for invoking the service APIs. The `New` and `NewFromConfig` each provide the same set of configurable options for constructing a service client, but provide slightly different construction patterns that we will look at in the following sections.

NewFromConfig

`NewFromConfig` function provides a consistent interface for constructing service clients using the aws.Config. An `aws.Config` can be loaded using the config.LoadDefaultConfig. For more information on constructing an `aws.Config`, see Configure the SDK. The following example shows how to construct an Amazon S3 service client using the `aws.Config`and the `NewFromConfig` function:

```
import "context"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/service/s3"

    // ...
```

```
    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic(err)
    }

    client := s3.NewFromConfig(cfg)
```

Overriding Configuration

`NewFromConfig` can take one or more functional arguments that can mutate a client's configuration `Options` struct. This allows you to make specific overrides such as changing the Region, or modifying service specific options such as Amazon S3 `UseAccelerate` option. For example:

```
import "context"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/service/s3"

    // ...

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic(err)
    }

    client := s3.NewFromConfig(cfg, func(o *s3.Options) {
        o.Region = "us-west-2"
        o.UseAccelerate = true
    })
```

Overrides to the client `Options` value is determined by the order that the functional arguments are given to `NewFromConfig`.

New

> **Note**
>
> New is considered a more advanced form of client construction. We recommend you use `NewFromConfig` for client construction, as it allows construction using the `aws.Config`

struct. This removes the need to construct an `Options` struct instance for each service client your application requires.

New function is a client constructor provides an interface for constructing clients using only the client packages `Options` struct for defining the client's configuration options. For example, to construct Amazon S3 client using New:

```
import "github.com/aws/aws-sdk-go-v2/aws"
    import "github.com/aws/aws-sdk-go-v2/credentials"
    import "github.com/aws/aws-sdk-go-v2/service/s3"

    // ...

    client := s3.New(s3.Options{
        Region:      "us-west-2",
        Credentials:
 aws.NewCredentialsCache(credentials.NewStaticCredentialsProvider(accessKey, secretKey,
 "")),
    })
```

Overriding Configuration

New can take one or more functional arguments that can mutate a client's configuration `Options` struct. This allows you to make specific overrides such as changing the Region or modifying service specific options such as Amazon S3 `UseAccelerate` option. For example:

```
import "github.com/aws/aws-sdk-go-v2/aws"
    import "github.com/aws/aws-sdk-go-v2/credentials"
    import "github.com/aws/aws-sdk-go-v2/service/s3"

    // ...

    options := s3.Options{
        Region:      "us-west-2",
        Credentials:
 aws.NewCredentialsCache(credentials.NewStaticCredentialsProvider(accessKey, secretKey,
 "")),
    }
```

```
    client := s3.New(options, func(o *s3.Options) {
        o.Region = "us-east-1"
        o.UseAccelerate = true
    })
```

Overrides to the client `Options` value is determined by the order that the functional arguments are given to `New`.

Calling Service Operations

After you have a service client instance, you can use it to call a service's operations. For example, to call the Amazon S3 `GetObject` operation:

```
response, err := client.GetObject(context.TODO(), &s3.GetObjectInput{
        Bucket: aws.String("amzn-s3-demo-bucket"),
        Key:    aws.String("obj-key"),
    })
```

When you call a service operation, the SDK synchronously validates the input, serializes the request, signs it with your credentials, sends it to AWS, and then deserializes a response or an error. In most cases, you can call service operations directly. Each service operation client method will return an operation response struct, and an error interface type. You should always check `error` type to determine if an error occurred before attempting to access the service operation's response struct.

Passing Parameters to a Service Operation

Each service operation method takes a context.Context value that can be used for setting request deadlines that will be honored by the SDK. In addition, each service operation will take a `<OperationName>Input` struct found in the service's respective Go package. You pass in API input parameters using the operation input struct.

Operation input structures can have input parameters such as the standard Go numerics, boolean, string, map, and list types. In more complex API operations a service might have more complex modeling of input parameters. These other types such as service specific structures and enum values are found in the service's `types` Go package.

In addition, services might distinguish between the default value of a Go type and whether the value was set or not by the user. In these cases, input parameters might require you to pass a pointer reference to the type in question. For standard Go types like numerics, boolean, and string there are `<Type>` and `From<Type>` convenience functions available in the aws to ease this conversion. For example, aws.String can be used to convert a `string` to a `*string` type for input parameters that require a pointer to a string. Inversely, aws.ToString can be used to transform a `*string` to a `string` while providing protection from dereferencing a nil pointer. The `To<Type>` functions are helpful when handling service responses.

Let's look at an example of how we can use an Amazon S3 client to call the `GetObject` API, and construct our input using the `types` package, and `aws.<Type>` helpers.

```
import "context"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/service/s3"
    import "github.com/aws/aws-sdk-go-v2/service/s3/types"

    // ...

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic(err)
    }

    client := s3.NewFromConfig(cfg)

    resp, err := client.GetObject(context.TODO(), &s3.GetObjectInput{
        Bucket:       aws.String("amzn-s3-demo-bucket"),
        Key:          aws.String("keyName"),
        RequestPayer: types.RequestPayerRequester,
    })
```

Overriding Client Options For Operation Call

Similar to how client operation options can be modified during construction of a client using functional arguments, the client options can be modified at the time the operation method is called by providing one or more functional arguments to the service operation method. This action is concurrency safe and will not affect other concurrent operations on the client.

For example, to override the client region from "us-west-2" to "us-east-1":

```
cfg, err := config.LoadDefaultConfig(context.TODO(), config.WithRegion("us-west-2"))
    if err != nil {
        log.Printf("error: %v", err)
        return
    }

    client := s3.NewFromConfig(cfg)

    params := &s3.GetObjectInput{
        // ...
    }

    resp, err := client.GetObject(context.TODO(), params, func(o *Options) {
        o.Region = "us-east-1"
    })
```

Handling Operation Responses

Each service operation has an associated output struct that contains the service's operation response members. The output struct follows the following naming pattern `<OperationName>Output`. Some operations might have no members defined for their operation output. After calling a service operation, the return `error` argument type should always be checked to determine if an error occurred while invoking the service operation. Errors returned can range from client-side input validation errors to service-side error responses returned to the client. The operation's output struct should not be accessed in the event that a non-nil error is returned by the client.

For example, to log an operation error and prematurely return from the calling function:

```
response, err := client.GetObject(context.TODO())
    if err != nil {
        log.Printf("GetObject error: %v", err)
        return
    }
```

For more information on error handling, including how to inspect for specific error types, see TODO

Responses with `io.ReadCloser`

Some API operations return a response struct that contain an output member that is an `io.ReadCloser`. This will be the case for API operations that expose some element of their output in the body of the HTTP response itself.

For example, Amazon S3 `GetObject` operation returns a response whose `Body` member is an `io.ReadCloser` for accessing the object payload.

> **Warning**
>
> You MUST ALWAYS `Close()` any `io.ReadCloser` output members, regardless of whether you have consumed its content. Failure to do so can leak resources and potentially create issues with reading response bodies for operations called in the future.

```
resp, err := s3svc.GetObject(context.TODO(), &s3.GetObjectInput{...})
    if err != nil {
        // handle error
        return
    }
    // Make sure to always close the response Body when finished
    defer resp.Body.Close()

    decoder := json.NewDecoder(resp.Body)
    if err := decoder.Decode(&myStruct); err != nil {
        // handle error
        return
    }
```

Response Metadata

All service operation output structs include a `ResultMetadata` member of type middleware.Metadata. `middleware.Metadata` is used by the SDK middleware to provide additional information from a service response that is not modeled by the service. This includes metadata like the `RequestID`. For example, to retrieve the `RequestID` associated with a service response to assist AWS Support in troubleshooting a request:

```
import "fmt"
```

```
    import "log"
    import "github.com/aws/aws-sdk-go-v2/aws/middleware"
    import "github.com/aws/aws-sdk-go-v2/service/s3"

    // ..

    resp, err := client.GetObject(context.TODO(), &s3.GetObjectInput{
        // ...
    })
    if err != nil {
        log.Printf("error: %v", err)
        return
    }

    requestID, ok := middleware.GetRequestIDMetadata(resp.ResultMetadata)
    if !ok {
        fmt.Println("RequestID not included with request")
    }

    fmt.Printf("RequestID: %s\n", requestID)
```

Concurrently Using Service Clients

You can create goroutines that concurrently use the same service client to send multiple requests. You can use a service client with as many goroutines as you want.

In the following example, an Amazon S3 service client is used in multiple goroutines. This example concurrently uploads two objects to an Amazon S3 bucket.

```
import "context"
    import "log"
    import "strings"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/service/s3"

    // ...

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        log.Printf("error: %v", err)
        return
```

```
    }

    client := s3.NewFromConfig(cfg)

    type result struct {
        Output *s3.PutObjectOutput
        Err    error
    }

    results := make(chan result, 2)

    var wg sync.WaitGroup
    wg.Add(2)

    go func() {
    defer wg.Done()
        output, err := client.PutObject(context.TODO(), &s3.PutObjectInput{
            Bucket: aws.String("amzn-s3-demo-bucket"),
            Key:    aws.String("foo"),
            Body:   strings.NewReader("foo body content"),
        })
        results <- result{Output: output, Err: err}
    }()

    go func() {
        defer wg.Done()
        output, err := client.PutObject(context.TODO(), &s3.PutObjectInput{
            Bucket: aws.String("amzn-s3-demo-bucket"),
            Key:    aws.String("bar"),
            Body:   strings.NewReader("bar body content"),
        })
        results <- result{Output: output, Err: err}
    }()

    wg.Wait()

    close(results)

    for result := range results {
        if result.Err != nil {
            log.Printf("error: %v", result.Err)
            continue
        }
        fmt.Printf("etag: %v", aws.ToString(result.Output.ETag))
```

```
    }
```

Using Operation Paginators

Typically, when you retrieve a list of items, you might need to check the output struct for a token or marker to confirm whether the AWS service returned all results from your request. If the token or marker is present, you use it to request the next page of results. Instead of managing these tokens or markers, you can use the service package's available paginator types.

Paginator helpers are available for supported service operations, and can be found in the service client's Go package. To construct a paginator for a supported operation, use the `New<OperationName>Paginator` function. Paginator construct functions take the service `Client`, the operation's `<OperationName>Input` input parameters, and an optional set of functional arguments allowing you to configure other optional paginator settings.

The returned operation paginator type provides a convenient way to iterate over a paginated operation until you have reached the last page, or you have found the item(s) that your application was searching for. A paginator type has two methods: `HasMorePages` and `NextPage`. `HasMorePages` returns a boolean value of `true` if the first page has not been retrieved, or if additional pages available to retrieve using the operation. To retrieve the first or subsequent pages of the operation, the `NextPage` operation must be called. `NextPage` takes `context.Context` and returns the operation output and any corresponding error. Like the client operation method return parameters, the return error should always be checked before attempting to use the returned response structure. See Handling Operation Responses.

The following example uses the `ListObjectsV2` paginator to list up to three pages of object keys from the `ListObjectV2`operation. Each page consists of up to 10 keys, which is defined by the `Limit` paginator option.

```
import "context"
    import "log"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/aws"
    import "github.com/aws/aws-sdk-go-v2/service/s3"

    // ...

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
```

```
        log.Printf("error: %v", err)
        return
    }

    client := s3.NewFromConfig(cfg)

    params := &s3.ListObjectsV2Input{
        Bucket: aws.String("amzn-s3-demo-bucket"),
    }

    paginator := s3.NewListObjectsV2Paginator(client, params, func(o
*s3.ListObjectsV2PaginatorOptions) {
        o.Limit = 10
    })

    pageNum := 0
    for paginator.HasMorePages() && pageNum < 3 {
        output, err := paginator.NextPage(context.TODO())
        if err != nil {
            log.Printf("error: %v", err)
            return
        }
        for _, value := range output.Contents {
            fmt.Println(*value.Key)
        }
        pageNum++
    }
```

Similar to client operation method, the client options like the request Region can be modified by providing one or more functional arguments to `NextPage`. For more information about overriding client options when calling an operation, see Overriding Client Options For Operation Call.

Using Waiters

When interacting with AWS APIs that are asynchronous, you often need to wait for a particular resource to become available in order to perform further actions on it.

For example, the Amazon DynamoDB `CreateTable` API returns immediately with a TableStatus of CREATING, and you can't invoke read or write operations until the table status has been transitioned to `ACTIVE`.

Writing logic to continuously poll the table status can be cumbersome and error-prone. The waiters help take the complexity out of it and are simple APIs that handle the polling task for you.

For example, you can use waiters to poll if a DynamoDB table is created and ready for a write operation.

```
import "context"
    import "fmt"
    import "log"
    import "time"
    import "github.com/aws/aws-sdk-go-v2/aws"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/service/dynamodb"

    // ...

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        log.Printf("error: %v", err)
        return
    }

    client := dynamodb.NewFromConfig(cfg)

    // we create a waiter instance by directly passing in a client
    // that satisfies the waiters client Interface.
    waiter :=  dynamodb.NewTableExistsWaiter(client)

    // params is the input to api operation used by the waiter
    params := &dynamodb.DescribeTableInput {
        TableName: aws.String("test-table")
    }

    // maxWaitTime is the maximum wait time, the waiter will wait for
    // the resource status.
    maxWaitTime := 5 * time.Minutes

    // Wait will poll until it gets the resource status, or max wait time
    // expires.
    err := waiter.Wait(context.TODO(), params, maxWaitTime)
    if err != nil {
        log.Printf("error: %v", err)
        return
```

```
    }
    fmt.Println("Dynamodb table is now ready for write operations")
```

Overriding waiter configuration

By default, the SDK uses the minimum delay and maximum delay value configured with optimal values defined by AWS services for different APIs. You can override waiter configuration by providing functional options during waiter construction, or when invoking a waiter operation.

For example, to override waiter configuration during waiter construction

```
import "context"
    import "fmt"
    import "log"
    import "time"
    import "github.com/aws/aws-sdk-go-v2/aws"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/service/dynamodb"

    // ...

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        log.Printf("error: %v", err)
        return
    }

    client := dynamodb.NewFromConfig(cfg)

    // we create a waiter instance by directly passing in a client
    // that satisfies the waiters client Interface.
    waiter :=  dynamodb.NewTableExistsWaiter(client, func (o
 *dynamodb.TableExistsWaiterOptions) {

        // override minimum delay to 10 seconds
        o.MinDelay = 10 * time.Second

        // override maximum default delay to 300 seconds
        o.MaxDelay = 300 * time.Second
    })
```

The `Wait` function on each waiter also takes in functional options. Similar to the above example, you can override waiter configuration per `Wait` request.

```
// params is the input to api operation used by the waiter
    params := &dynamodb.DescribeTableInput {
        TableName: aws.String("test-table")
    }

    // maxWaitTime is the maximum wait time, the waiter will wait for
    // the resource status.
    maxWaitTime := 5 * time.Minutes

    // Wait will poll until it gets the resource status, or max wait time
    // expires.
    err := waiter.Wait(context.TODO(), params, maxWaitTime, func (o
 *dynamodb.TableExistsWaiterOptions) {

        // override minimum delay to 5 seconds
        o.MinDelay = 5 * time.Second

        // override maximum default delay to 120 seconds
        o.MaxDelay = 120 * time.Second
    })
    if err != nil {
        log.Printf("error: %v", err)
        return
    }
    fmt.Println("Dynamodb table is now ready for write operations")
```

Advanced waiter configuration overrides

You can additionally customize the waiter default behavior by providing a custom retryable function. The waiter-specific options also provides `APIOptions` to customize operation middlewares.

For example, to configure advanced waiter overrides.

```
import "context"
    import "fmt"
    import "log"
    import "time"
```

```
    import "github.com/aws/aws-sdk-go-v2/aws"
    import "github.com/aws/aws-sdk-go-v2/config"
    import "github.com/aws/aws-sdk-go-v2/service/dynamodb"
    import "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
    // ...

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        log.Printf("error: %v", err)
        return
    }

    client := dynamodb.NewFromConfig(cfg)

    // custom retryable defines if a waiter state is retryable or a terminal state.
    // For example purposes, we will configure the waiter to not wait
    // if table status is returned as `UPDATING`
    customRetryable := func(ctx context.Context, params *dynamodb.DescribeTableInput,
        output *dynamodb.DescribeTableOutput, err error) (bool, error) {
        if output.Table != nil {
            if output.Table.TableStatus == types.TableStatusUpdating {
                // if table status is `UPDATING`, no need to wait
                return false, nil
            }
        }
    }

    // we create a waiter instance by directly passing in a client
    // that satisfies the waiters client Interface.
    waiter :=  dynamodb.NewTableExistsWaiter(client, func (o
*dynamodb.TableExistsWaiterOptions) {

        // override the service defined waiter-behavior
        o.Retryable = customRetryable
    })
```

Handling Errors in the AWS SDK for Go V2

The AWS SDK for Go returns errors that satisfy the Go `error` interface type. You can use the `Error()` method to get a formatted string of the SDK error message without any special handling. Errors returned by the SDK may implement an `Unwrap` method. The `Unwrap` method is used

by the SDK to provide additional contextual information to errors, while providing access to the underlying error or chain of errors. The `Unwrap` method should be used with the errors.As to handle unwrapping error chains.

It is important that your application check whether an error occurred after invoking a function or method that can return an `error` interface type. The most basic form of error handling looks similar to the following example:

```
if err != nil {
    // Handle error
    return
}
```

Logging Errors

The simplest form of error handling is traditionally to log or print the error message before returning or exiting from the application.

```
import "log"

// ...

if err != nil {
    log.Printf("error: %s", err.Error())
    return
}
```

Service Client Errors

The SDK wraps all errors returned by service clients with the smithy.OperationError error type. `OperationError` provides contextual information about the service name and operation that is associated with an underlying error. This information can be useful for applications that perform batches of operations to one or more services, with a centralized error handling mechanism. Your application can use `errors.As` to access this `OperationError` metadata.

```
import "log"
import "github.com/aws/smithy-go"

// ...
```

```
if err != nil {
    var oe *smithy.OperationError
    if errors.As(err, &oe) {
        log.Printf("failed to call service: %s, operation: %s, error: %v",
 oe.Service(), oe.Operation(), oe.Unwrap())
    }
    return
}
```

API Error Responses

Service operations can return modeled error types to indicate specific errors. These modeled types can be used with `errors.As` to unwrap and determine if the operation failure was due to a specific error. For example, Amazon S3 `CreateBucket` can return a BucketAlreadyExists error if a bucket of the same name already exists.

For example, to check if an error was a `BucketAlreadyExists` error:

```
import "log"
import "github.com/aws/aws-sdk-go-v2/service/s3/types"

// ...

if err != nil {
    var bne *types.BucketAlreadyExists
    if errors.As(err, &bne) {
        log.Println("error:", bne)
    }
    return
}
```

All service API response errors implement the smithy.APIError interface type. This interface can be used to handle both modeled or un-modeled service error responses. This type provides access to the error code and message returned by the service. Additionally, this type provides indication of whether the fault of the error was due to the client or server if known.

```
import "log"
import "github.com/aws/smithy-go"

// ...
```

```
if err != nil {
    var ae smithy.APIError
    if errors.As(err, &ae) {
        log.Printf("code: %s, message: %s, fault: %s", ae.ErrorCode(),
 ae.ErrorMessage(), ae.ErrorFault().String())
    }
    return
}
```

Retrieving Request Identifiers

When working with AWS Support, you may be asked to provide the request identifier that identifies the request you are attempting to troubleshoot. You can use http.ResponseError and use the `ServiceRequestID()` method to retrieve the request identifier associated with error response.

```
import "log"
import awshttp "github.com/aws/aws-sdk-go-v2/aws/transport/http"

// ...

if err != nil {
    var re *awshttp.ResponseError
    if errors.As(err, &re) {
        log.Printf("requestID: %s, error: %v", re.ServiceRequestID(), re.Unwrap());
    }
    return
}
```

Amazon S3 Request Identifiers

Amazon S3 requests contain additional identifiers that can be used to assist AWS Support with troubleshooting your request. You can use s3.ResponseError and call `ServiceRequestID()` and `ServiceHostID()` to retrieve the request ID and host ID.

```
import "log"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

if err != nil {
    var re s3.ResponseError
```

```
    if errors.As(err, &re) {
        log.Printf("requestID: %s, hostID: %s request failure", re.ServiceRequestID(),
 re.ServiceHostID());
    }
    return
}
```

Use the AWS SDK for Go v2 with AWS services

To make calls to an AWS service, you must first construct a service client instance. A service client provides low-level access to every API action for that service. For example, you create an Amazon S3 service client to make calls to Amazon S3 APIs.

When you call service operations, you pass in input parameters as a struct. A successful call will result in an output struct containing the service API response. For example, after you successfully call an Amazon S3 create bucket action, the action returns an output struct with the bucket's location.

For the list of service clients, including their methods and parameters, see the AWS SDK for Go API Reference.

Data integrity protection with checksums

Amazon Simple Storage Service (Amazon S3) provides the ability to specify a checksum when you upload an object. When you specify a checksum, it is stored with the object and can be validated when the object is downloaded.

Checksums provide an additional layer of data integrity when you transfer files. With checksums, you can verify data consistency by confirming that the received file matches the original file. For more information about checksums with Amazon S3, see the Amazon Simple Storage Service User Guide including the supported algorithms.

You have the flexibility to choose the algorithm that best fits your needs and let the SDK calculate the checksum. Alternatively, you can provide a pre-computed checksum value by using one of the supported algorithms.

> **Note**
>
> Beginning with version v1.74.1 of the Amazon S3 module, the SDK provides default integrity protections by automatically calculating a CRC32 checksum for uploads. The SDK calculates this checksum if you don't provide a precalculated checksum value or if you don't specify an algorithm that the SDK should use to calculate a checksum.
> The SDK also provides global settings for data integrity protections that you can set externally, which you can read about in the AWS SDKs and Tools Reference Guide.

We discuss checksums in two request phases: uploading an object and downloading an object.

Upload an object

When you upload an object with the `putObject` method and provide a checksum algorithm, the SDK computes the checksum for the specified algorithm.

The following code snippet shows a request to upload an object with a CRC32 checksum. When the SDK sends the request, it calculates the CRC32 checksum and uploads the object. Amazon S3 validates the integrity of the content by calculating the checksum and comparing it to the checksum provided by the SDK. Amazon S3 then stores the checksum with the object.

```
out, err := s3Client.PutObject(context.Background(), &s3.PutObjectInput{
     Bucket:            aws.String("bucket"),
     Key:               aws.String("key"),
     ChecksumAlgorithm: types.ChecksumAlgorithmCrc32,
     Body:              strings.NewReader("Hello World"),
 })
```

If you don't provide a checksum algorithm with the request, the checksum behavior varies depending on the version of the SDK that you use as shown in the following table.

Checksum behavior when no checksum algorithm is provided

Amazon S3 module version of AWS SDK for Go	Checksum behavior
Earlier than v1.74.1	The SDK doesn't automatically calculate a CRC-based checksum and provide it in the request.
v1.74.1 or later	The SDK uses the CRC32 algorithm to calculate the checksum and provides it in the request. Amazon S3 validates the integrity of the transfer by computing its own CRC32 checksum and compares it to the checksum provided by the SDK. If the checksums match, the checksum is saved with the object.

Use a pre-calculated checksum value

A pre-calculated checksum value provided with the request disables automatic computation by the SDK and uses the provided value instead.

The following example shows a request with a pre-calculated SHA256 checksum.

```
out, err := s3Client.PutObject(context.Background(), &s3.PutObjectInput{
     Bucket:        aws.String("bucket"),
     Key:           aws.String("key"),
     ChecksumCRC32: aws.String("checksumvalue"),
     Body:          strings.NewReader("Hello World"),
 })
```

If Amazon S3 determines the checksum value is incorrect for the specified algorithm, the service returns an error response.

Multipart uploads

You can also use checksums with multipart uploads.

The AWS SDK for Go provides two options to use checksums with multipart uploads. The first option uses the transfer manager that specifies the CRC32 algorithm for the upload.

```
s3Client := s3.NewFromConfig(cfg)
     transferManager := manager.NewUploader(s3Client)
     out, err := transferManager.Upload(context.Background(), &s3.PutObjectInput{
             Bucket:            aws.String("bucket"),
             Key:               aws.String("key"),
             Body:              large file to trigger multipart upload,
             ChecksumAlgorithm: types.ChecksumAlgorithmCrc32,
     })
```

If you don't provide a checksum algorithm when using the transfer manager for uploads, the SDK automatically calculates and checksum based on the CRC32 algorithm. The SDK performs this calculation for all versions of the SDK.

The second option uses the Amazon S3 client to perform the multipart upload. If you specify a checksum with this approach, you must specify the algorithm to use on the initiation of the upload. You must also specify the algorithm for each part request and provide the checksum calculated for each part after it is uploaded.

```
s3Client := s3.NewFromConfig(cfg)
    createMultipartUploadOutput, err :=
 s3Client.CreateMultipartUpload(context.Background(), &s3.CreateMultipartUploadInput{
            Bucket:            aws.String("bucket"),
            Key:               aws.String("key"),
            ChecksumAlgorithm: types.ChecksumAlgorithmCrc32,
         })
    if err != nil {
            log.Fatal("err create multipart upload ", err)
    }

    var partsBody []io.Reader // this is just an example parts content, you should
 load your target file in your code
    partNum := int32(1)
    var completedParts []types.CompletedPart
    for _, body := range partsBody {
        uploadPartOutput, err := s3Client.UploadPart(context.Background(),
 &s3.UploadPartInput{
            Bucket:            aws.String("bucket"),
            Key:               aws.String("key"),
            ChecksumAlgorithm: types.ChecksumAlgorithmCrc32,
            Body:              body,
            PartNumber:        aws.Int32(partNum),
            UploadId:          createMultipartUploadOutput.UploadId,
        })
        if err != nil {
            log.Fatal("err upload part ", err)
        }

        completedParts = append(completedParts, types.CompletedPart{
            PartNumber:    aws.Int32(partNum),
            ETag:          uploadPartOutput.ETag,
            ChecksumCRC32: uploadPartOutput.ChecksumCRC32,
        })
        partNum++
    }

    completeMultipartUploadOutput, err :=
 s3Client.CompleteMultipartUpload(context.Background(),
 &s3.CompleteMultipartUploadInput{
        Bucket:   aws.String("bucket"),
        Key:      aws.String("key"),
        UploadId: createMultipartUploadOutput.UploadId,
```

```
        MultipartUpload: &types.CompletedMultipartUpload{
            Parts: completedParts,
        },
    })
    if err != nil {
        log.Fatal("err complete multipart upload ", err)
    }
```

Download an object

When you use the GetObject method to download an object, the SDK automatically validates the checksum when the `ChecksumMode` field of `GetObjectInput` is set to `types.ChecksumModeEnabled`.

The request in the following snippet directs the SDK to validate the checksum in the response by calculating the checksum and comparing the values.

```
out, err := s3Client.GetObject(context.Background(), &s3.GetObjectInput{
    Bucket:       aws.String("bucket"),
    Key:          aws.String("key"),
    ChecksumMode: types.ChecksumModeEnabled,
 })
```

If the object wasn't uploaded with a checksum, no validation takes place.

Using the AWS SDK for Go Utilities

The AWS SDK for Go includes the following utilities to help you more easily use AWS services. Find the SDK utilities in their related AWS service package.

Amazon RDS Utilities

IAM Authentication

The auth package provides utilities for generating authentication tokens for connecting to Amazon RDS MySQL and PostgreSQL database instances. Using the BuildAuthToken method, you generate a database authorization token by providing the database endpoint, AWS Region, username, and a aws.CredentialProvider implementation that returns IAM credentials with permission to connect to the database using IAM database authentication. To learn more about configuring Amazon RDS with IAM authentication, see the following Amazon RDS Developer Guide resources:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

The following example shows how to generate an authentication token to connect to an Amazon RDS database:

```
import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/feature/rds/auth"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    panic("configuration error: " + err.Error())
}

authenticationToken, err := auth.BuildAuthToken(
    context.TODO(),
    "mydb.123456789012.us-east-1.rds.amazonaws.com:3306", // Database Endpoint (With
 Port)
```

```
    "us-east-1", // AWS Region
    "jane_doe", // Database Account
    cfg.Credentials,
)
if err != nil {
    panic("failed to create authentication token: " + err.Error())
}
```

Amazon CloudFront Utilities

Amazon CloudFront URL Signer

The Amazon CloudFront URL signer simplifies the process of creating signed URLs. A signed URL includes information, such as an expiration date and time, that enables you to control access to your content. Signed URLs are useful when you want to distribute content through the internet, but want to restrict access to certain users (for example, to users who have paid a fee).

To sign a URL, create a `URLSigner` instance with your CloudFront key pair ID and the associated private key. Then call the `Sign` or `SignWithPolicy` method and include the URL to sign. For more information about Amazon CloudFront key pairs, see Creating CloudFront Key Pairs for Your Trusted Signers in the CloudFront Developer Guide.

The following example creates a signed URL that's valid for one hour after it is created.

```
import "github.com/aws/aws-sdk-go-v2/feature/cloudfront/sign"

// ...

signer := sign.NewURLSigner(keyID, privKey)

signedURL, err := signer.Sign(rawURL, time.Now().Add(1*time.Hour))
if err != nil {
    log.Fatalf("Failed to sign url, err: %s\n", err.Error())
    return
}
```

For more information about the signing utility, see the sign package in the AWS SDK for Go API Reference.

Amazon EC2 Instance Metadata Service

You can use the AWS SDK for Go to access the Amazon EC2 Instance Metadata Service. The feature/ec2/imds Go package provides a Client type that can be used to access the Amazon EC2 Instance Metadata Service. The `Client` and associated operations can be used similar to the other AWS service clients provided by the SDK. To learn more information on how to configure the SDK, and use service clients see Configure the SDK and Use the AWS SDK for Go v2 with AWS services.

The client can help you easily retrieve information about instances on which your applications run, such as its AWS Region or local IP address. Typically, you must create and submit HTTP requests to retrieve instance metadata. Instead, create an `imds.Client` to access the Amazon EC2 Instance Metadata Service using a programmatic client like other AWS Services.

For example to construct a client:

```
import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/feature/ec2/imds"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    log.Printf("error: %v", err)
    return
}

client := imds.NewFromConfig(cfg)
```

Then use the service client to retrieve information from a metadata category such as `local-ipv4` (the private IP address of the instance).

```
localIp, err := client.GetMetadata(context.TODO(), &imds.GetMetadataInput{
    Path: "local-ipv4",
})
if err != nil {
    log.Printf("Unable to retrieve the private IP address from the EC2 instance: %s\n",
 err)
    return
}
content, _ := io.ReadAll(localIp.Content)
```

```
fmt.Printf("local-ip: %v\n", string(content))
```

For a list of all metadata categories, see Instance metadata categories in the Amazon EC2 User Guide.

Amazon S3 Utilities

Amazon S3 Transfer Managers

The Amazon S3 upload and download managers can break up large objects, so they can be transferred in multiple parts, in parallel. This makes it easy to resume interrupted transfers.

Amazon S3 Upload Manager

The Amazon S3 upload manager determines if a file can be split into smaller parts and uploaded in parallel. You can customize the number of parallel uploads and the size of the uploaded parts.

The following example uses the Amazon S3 `Uploader` to upload a file. Using `Uploader` is similar to the `s3.PutObject()` operation.

```
import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"
import "github.com/aws/aws-sdk-go-v2/feature/s3/manager"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    log.Printf("error: %v", err)
    return
}

client := s3.NewFromConfig(cfg)

uploader := manager.NewUploader(client)
result, err := uploader.Upload(context.TODO(), &s3.PutObjectInput{
    Bucket: aws.String("amzn-s3-demo-bucket"),
    Key:    aws.String("my-object-key"),
    Body:   uploadFile,
})
```

Configuration Options

When you instantiate an `Uploader` instance using NewUploader, you can specify several configuration options to customize how objects are uploaded. Options are overridden by providing one or more arguments to `NewUploader`. These options include:

- `PartSize` – Specifies the buffer size, in bytes, of each part to upload. The minimum size per part is 5 MiB.
- `Concurrency` – Specifies the number of parts to upload in parallel.
- `LeavePartsOnError` – Indicates whether to leave successfully uploaded parts in Amazon S3.

The `Concurrency` value limits the concurrent number of part uploads that can occur for a given `Upload` call. This is not a global client concurrency limit. Tweak the `PartSize` and `Concurrency` configuration values to find the optimal configuration. For example, systems with high-bandwidth connections can send bigger parts and more uploads in parallel.

For example, your application configures `Uploader` with a `Concurrency` of setting of `5`. If your application then calls `Upload` from two different goroutines, the result is `10` concurrent part uploads (2 goroutines * 5 `Concurrency`).

> **Warning**
>
> Your application is expected to limit the concurrent calls to `Upload` to prevent application resource exhaustion.

Below is an example to set the default part size during `Uploader` creation:

```
uploader := manager.NewUploader(client, func(u *Uploader) {
    u.PartSize = 10 * 1024 * 1024, // 10 MiB
})
```

For more information about `Uploader` and its configurations, see Uploader in the AWS SDK for Go API Reference.

PutObjectInput Body Field (io.ReadSeeker vs. io.Reader)

The Body field of the `s3.PutObjectInput` struct is an `io.Reader` type. However, this field can be populated with a type that satisfies both the `io.ReadSeeker` and `io.ReaderAt` interface to

improve application resource utilization of the host environment. The following example creates the type `ReadSeekerAt` that satisfies both interfaces:

```
type ReadSeekerAt interface {
    io.ReadSeeker
    io.ReaderAt
}
```

For `io.Reader` types, the bytes of the reader must be buffered in memory before the part can be uploaded. When you increase the `PartSize` or `Concurrency` value, the required memory (RAM) for the `Uploader` increases significantly. The required memory is approximately *`PartSize`* * *`Concurrency`*. For example, specifying 100 MB for `PartSize` and 10 for `Concurrency`, requires at least 1 GB.

Because an `io.Reader` type cannot determine its size before reading its bytes, `Uploader` cannot calculate how many parts will be uploaded. Consequently, `Uploader` can reach the Amazon S3 upload limit of 10,000 parts for large files if you set the `PartSize` too low. If you try to upload more than 10,000 parts, the upload stops and returns an error.

For body values that implement the `ReadSeekerAt` type, the `Uploader` doesn't buffer the body contents in memory before sending it to Amazon S3. `Uploader` calculates the expected number of parts before uploading the file to Amazon S3. If the current value of `PartSize` requires more than 10,000 parts to upload the file, `Uploader` increases the part size value so that fewer parts are required.

Handling Failed Uploads

If an upload to Amazon S3 fails, by default, `Uploader` uses the Amazon S3 `AbortMultipartUpload` operation to remove the uploaded parts. This functionality ensures that failed uploads do not consume Amazon S3 storage.

You can set `LeavePartsOnError` to true so that the `Uploader` doesn't delete successfully uploaded parts. This is useful for resuming partially completed uploads. To operate on uploaded parts, you must get the `UploadID` of the failed upload. The following example demonstrates how to use the `manager.MultiUploadFailure` error interface type to get the `UploadID`.

```
result, err := uploader.Upload(context.TODO(), &s3.PutObjectInput{
    Bucket: aws.String("amzn-s3-demo-bucket"),
    Key:    aws.String("my-object-key"),
    Body:   uploadFile,
```

```
})
output, err := u.upload(input)
if err != nil {
    var mu manager.MultiUploadFailure
    if errors.As(err, &mu) {
        // Process error and its associated uploadID
        fmt.Println("Error:", mu)
        _ = mu.UploadID() // retrieve the associated UploadID
    } else {
        // Process error generically
        fmt.Println("Error:", err.Error())
    }
    return
}
```

Overriding Uploader Options Per Upload

You can override the `Uploader` options when calling `Upload` by providing one or more arguments to the method. These overrides are concurrency-safe modifications and do not affect ongoing uploads, or subsequent `Upload` calls to the manager. For example, to override the `PartSize` configuration for a specific upload request:

```
params := &s3.PutObjectInput{
    Bucket: aws.String("amzn-s3-demo-bucket"),
    Key:    aws.String("my-key"),
    Body:   myBody,
}
resp, err := uploader.Upload(context.TODO(), params, func(u *manager.Uploader) {
    u.PartSize = 10 * 1024 * 1024, // 10 MiB
})
```

Examples

Upload a Folder to Amazon S3

The following example uses the `path/filepath` package to recursively gather a list of files and upload them to the specified Amazon S3 bucket. The keys of the Amazon S3 objects are prefixed with the file's relative path.

```
package main

import (
```

```
    "context"
    "log"
    "os"
    "path/filepath"

    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/s3/manager"
    "github.com/aws/aws-sdk-go-v2/service/s3"
)

var (
    localPath string
    bucket    string
    prefix    string
)

func init() {
    if len(os.Args) != 4 {
        log.Fatalln("Usage:", os.Args[0], "<local path> <bucket> <prefix>")
    }
    localPath = os.Args[1]
    bucket = os.Args[2]
    prefix = os.Args[3]
}

func main() {
    walker := make(fileWalk)
    go func() {
        // Gather the files to upload by walking the path recursively
        if err := filepath.Walk(localPath, walker.Walk); err != nil {
            log.Fatalln("Walk failed:", err)
        }
        close(walker)
    }()

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        log.Fatalln("error:", err)
    }

    // For each file found walking, upload it to Amazon S3
    uploader := manager.NewUploader(s3.NewFromConfig(cfg))
    for path := range walker {
```

```
        rel, err := filepath.Rel(localPath, path)
        if err != nil {
            log.Fatalln("Unable to get relative path:", path, err)
        }
        file, err := os.Open(path)
        if err != nil {
            log.Println("Failed opening file", path, err)
            continue
        }
        defer file.Close()
        result, err := uploader.Upload(context.TODO(), &s3.PutObjectInput{
            Bucket: &bucket,
            Key:    aws.String(filepath.Join(prefix, rel)),
            Body:   file,
        })
        if err != nil {
            log.Fatalln("Failed to upload", path, err)
        }
        log.Println("Uploaded", path, result.Location)
    }
}

type fileWalk chan string

func (f fileWalk) Walk(path string, info os.FileInfo, err error) error {
    if err != nil {
        return err
    }
    if !info.IsDir() {
        f <- path
    }
    return nil
}
```

Download Manager

The Amazon S3 Downloader manager determines if a file can be split into smaller parts and downloaded in parallel. You can customize the number of parallel downloads and the size of the downloaded parts.

Example: Download a File

The following example uses the Amazon S3 `Downloader` to download a file. Using `Downloader` is similar to the s3.GetObject operation.

```
import "context"
import "github.com/aws/aws-sdk-go-v2/aws"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"
import "github.com/aws/aws-sdk-go-v2/feature/s3/manager"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    log.Println("error:", err)
    return
}

client := s3.NewFromConfig(cfg)

downloader := manager.NewDownloader(client)
numBytes, err := downloader.Download(context.TODO(), downloadFile, &s3.GetObjectInput{
    Bucket: aws.String("amzn-s3-demo-bucket"),
    Key:    aws.String("my-key"),
})
```

The `downloadFile` parameter is an `io.WriterAt` type. The `WriterAt` interface enables the `Downloader` to write multiple parts of the file in parallel.

Configuration Options

When you instantiate a `Downloader` instance, you can specify configuration options to customize how objects are downloaded:

- `PartSize` – Specifies the buffer size, in bytes, of each part to download. The minimum size per part is 5 MB.
- `Concurrency` – Specifies the number of parts to download in parallel.

The `Concurrency` value limits the concurrent number of part download that can occur for a given `Download` call. This is not a global client concurrency limit. Tweak the `PartSize` and

`Concurrency` configuration values to find the optimal configuration. For example, systems with high-bandwidth connections can receive bigger parts and more downloads in parallel.

For example, your application configures `Downloader` with a `Concurrency` of `5`. Your application then calls `Download` from two different goroutines, the result will be `10` concurrent part downloads (2 goroutines * 5 `Concurrency`).

> **Warning**
>
> Your application is expected to limit the concurrent calls to `Download` to prevent application resource exhaustion.

For more information about `Downloader` and its other configuration options, see manager.Downloader in the AWS SDK for Go API Reference.

Overriding Downloader Options Per Download

You can override the `Downloader` options when calling `Download` by providing one or more functional arguments to the method. These overrides are concurrency safe modifications and do not affect ongoing uploads, or subsequent `Download` calls to the manager. For example, to override the `PartSize` configuration for a specific upload request:

```
params := &s3.GetObjectInput{
    Bucket: aws.String("amzn-s3-demo-bucket"),
    Key:    aws.String("my-key"),
}
resp, err := downloader.Download(context.TODO(), targetWriter, params, func(u
 *manager.Downloader) {
    u.PartSize = 10 * 1024 * 1024, // 10 MiB
})
```

Examples

Download All Objects in a Bucket

The following example uses pagination to gather a list of objects from an Amazon S3 bucket. Then it downloads each object to a local file.

```
package main
```

```
import (
    "context"
    "fmt"
    "log"
    "os"
    "path/filepath"

    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/s3/manager"
    "github.com/aws/aws-sdk-go-v2/service/s3"
)

var (
    Bucket         = "amzn-s3-demo-bucket" // Download from this bucket
    Prefix         = "logs/"    // Using this key prefix
    LocalDirectory = "s3logs"   // Into this directory
)

func main() {
    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        log.Fatalln("error:", err)
    }

    client := s3.NewFromConfig(cfg)
    manager := manager.NewDownloader(client)

    paginator := s3.NewListObjectsV2Paginator(client, &s3.ListObjectsV2Input{
        Bucket: &Bucket,
        Prefix: &Prefix,
    })

    for paginator.HasMorePages() {
        page, err := paginator.NextPage(context.TODO())
        if err != nil {
            log.Fatalln("error:", err)
        }
        for _, obj := range page.Contents {
            if err := downloadToFile(manager, LocalDirectory, Bucket,
 aws.ToString(obj.Key)); err != nil {
                log.Fatalln("error:", err)
            }
        }
```

```
    }
}

func downloadToFile(downloader *manager.Downloader, targetDirectory, bucket, key
 string) error {
    // Create the directories in the path
    file := filepath.Join(targetDirectory, key)
    if err := os.MkdirAll(filepath.Dir(file), 0775); err != nil {
        return err
    }

    // Set up the local file
    fd, err := os.Create(file)
    if err != nil {
        return err
    }
    defer fd.Close()

    // Download the file using the AWS SDK for Go
    fmt.Printf("Downloading s3://%s/%s to %s...\n", bucket, key, file)
    _, err = downloader.Download(context.TODO(), fd, &s3.GetObjectInput{Bucket:
 &bucket, Key: &key})

    return err
}
```

GetBucketRegion

GetBucketRegion is a utility function for determining the AWS Region location of an Amazon S3 Bucket. `GetBucketRegion` takes an Amazon S3 client and uses it to determine the location of the requested Bucket within the AWS Partition associated with the client's configured Region.

For example, to find the Region for the Bucket *amzn-s3-demo-bucket*:

```
cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    log.Println("error:", err)
    return
}

bucket := "amzn-s3-demo-bucket"
region, err := manager.GetBucketRegion(ctx, s3.NewFromConfig(cfg), bucket)
if err != nil {
```

```
    var bnf manager.BucketNotFound
    if errors.As(err, &bnf) {
        log.Printf("unable to find bucket %s's Region\n", bucket)
    } else {
        log.Println("error:", err)
    }
    return
}
fmt.Printf("Bucket %s is in %s region\n", bucket, region)
```

If `GetBucketRegion` is not able to resolve the location of a Bucket, the function returns a BucketNotFound error type as shown in the example.

Unseekable Streaming Input

For API operations like `PutObject` and `UploadPart`, the Amazon S3 client expects the value of the `Body` input parameter to implement the io.Seeker interface by default. The `io.Seeker` interface is used by the client to determine the length of the value to upload, and to compute payload hash for the request signature. If the `Body` input parameter value does not implement `io.Seeker`, your application will receive an error.

```
operation error S3: PutObject, failed to compute payload hash: failed to seek
body to start, request stream is not seekable
```

You can change this behavior by modifying the operation method's Middleware using functional options. The WithAPIOptions helper returns a functional option for zero or more middleware mutators. To disable the client computing the payload hash and use Unsigned Payload request signature add v4.SwapComputePayloadSHA256ForUnsignedPayloadMiddleware.

```
resp, err := client.PutObject(context.TODO(), &s3.PutObjectInput{
    Bucket: &bucketName,
    Key: &objectName,
    Body: bytes.NewBuffer([]byte(`example object!`)),
    ContentLength: 15, // length of body
}, s3.WithAPIOptions(
    v4.SwapComputePayloadSHA256ForUnsignedPayloadMiddleware,
))
```

Warning

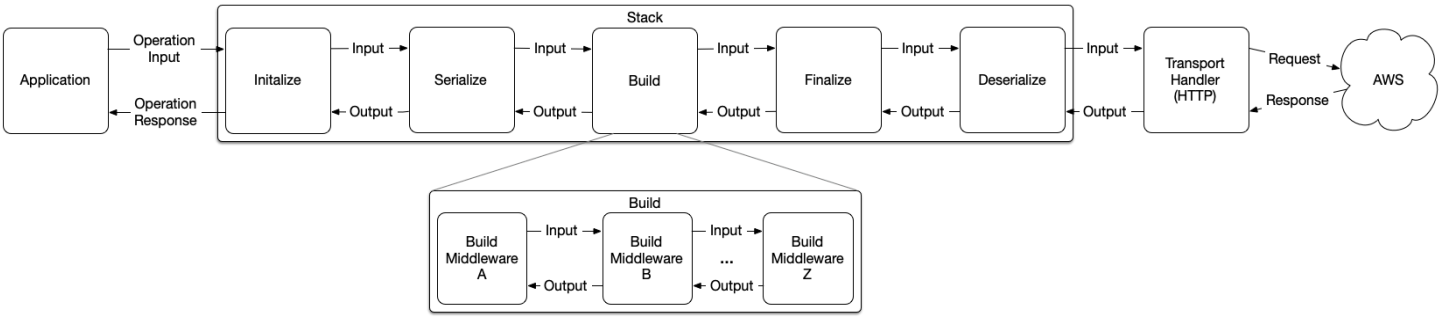
Amazon S3 requires the content length to be provided for all object's uploaded to a bucket. Since the `Body` input parameter does not implement `io.Seeker` interface, the client will not be able to compute the `ContentLength` parameter for the request. The parameter must be provided by the application. The request will fail if the `ContentLength` parameter is not provided.

Use the SDK's Amazon S3 Upload Manager for uploads that are not seekable and do not have a known length.

Customizing the AWS SDK for Go v2 Client Requests with Middleware

> **Warning**
>
> Modifying the client request pipeline can result in malformed/invalid requests, or can result in unexpected application errors. This functionality is meant for advanced uses cases not provided by the SDK interface by default.

You can customize AWS SDK for Go client requests by registering one or more middleware to a service operation's stack. The stack is composed of a series of steps: Initialize, Serialize, Build, Finalize, and Deserialize. Each step contains zero or more middleware that operate on that step's input and output types. The following diagram and table provide an overview of how an operation's request and response traverses the stack.



Stack Step	Description
Initialize	Prepares the input, and sets any default parameters as needed.
Serialize	Serializes the input to a protocol format suitable for the target transport layer.
Build	Attach additional metadata to the serialized input, such as HTTP Content-Length.

Stack Step	Description
Finalize	Final message preparation, including retries and authentication (SigV4 signing).
Deserialize	Deserialize responses from the protocol format into a structured type or error.

Each middleware within a given step must have a unique identifier, which is determined by the middleware's `ID` method. Middleware identifiers ensure that only one instance of a given middleware is registered to a step, and allows other step middleware to be inserted relative to it.

You attach step middleware by using a step's `Insert` or `Add` methods. You use `Add` to attach a middleware to the beginning of a step by specifying middleware.Before as the RelativePosition, and middleware.After to attach to the end of the step. You use `Insert` to attach a middleware to a step by inserting the middleware relative to another step middleware.

> **Warning**
>
> You must use the `Add` method to safely insert custom step middleware. Using `Insert` creates a dependency between your custom middleware, and the middleware that you are inserting relative to. The middleware within a stack step must be considered opaque to avoid breaking changes occurring to your application.

Writing a Custom Middleware

Each stack step has an interface that you must satisfy in order attach a middleware to a given step. You can use one of the provided *`Step`*`MiddlewareFunc` functions to quickly satisfy this interface. The following table outlines the steps, their interface, and the helper function that can be used to satisfy the interface.

Step	Interface	Helper Function
Initialize	InitializeMiddleware	InitializeMiddlewareFunc
Build	BuildMiddleware	BuildMiddlewareFunc

Step	Interface	Helper Function
Serialize	SerializeMiddleware	SerializeMiddlewareFunc
Finalize	FinalizeMiddleware	FinalizeMiddlewareFunc
Deserialize	DeserializeMiddleware	DeserializeMiddlewareFunc

The following examples show how you can write a custom middleware to populate the Bucket member of the Amazon S3 `GetObject` API calls if one is not provided. This middleware will be referenced in proceeding examples to show how to attach step middleware to the stack.

```
import "github.com/aws/smithy-go/aws"
import "github.com/aws/smithy-go/middleware"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

var defaultBucket = middleware.InitializeMiddlewareFunc("DefaultBucket", func(
    ctx context.Context, in middleware.InitializeInput, next
 middleware.InitializeHandler,
) (
    out middleware.InitializeOutput, metadata middleware.Metadata, err error,
) {
    // Type switch to check if the input is s3.GetObjectInput, if so and the bucket is
 not set, populate it with
    // our default.
    switch v := in.Parameters.(type) {
    case *s3.GetObjectInput:
        if v.Bucket == nil {
            v.Bucket = aws.String("amzn-s3-demo-bucket")
        }
    }

    // Middleware must call the next middleware to be executed in order to continue
 execution of the stack.
    // If an error occurs, you can return to prevent further execution.
    return next.HandleInitialize(ctx, in)
})
```

Attaching Middleware to All Clients

You can attach your custom step middleware to every client by adding the middleware using the `APIOptions` member of the aws.Config type. The following examples attaches the `defaultBucket` middleware to every client constructed using your applications `aws.Config` object:

```
import "context"
import "github.com/aws/aws-sdk-go-v2/aws"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"
import "github.com/aws/smithy-go/middleware"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    // handle error
}

cfg.APIOptions = append(cfg.APIOptions, func(stack *middleware.Stack) error {
    // Attach the custom middleware to the beginning of the Initialize step
    return stack.Initialize.Add(defaultBucket, middleware.Before)
})

client := s3.NewFromConfig(cfg)
```

Attaching Middleware to a Specific Operation

You can attach your custom step middleware to a specific client operation by modifying the client's `APIOptions` member using the variadic argument list for an operation. The following examples attaches the `defaultBucket` middleware to a specific Amazon S3 `GetObject` operation invocation:

```
import "context"
import "github.com/aws/aws-sdk-go-v2/aws"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"
import "github.com/aws/smithy-go/middleware"

// ...
```

```
// registerDefaultBucketMiddleware registers the defaultBucket middleware with the
 provided stack.
func registerDefaultBucketMiddleware(stack *middleware.Stack) error {
    // Attach the custom middleware to the beginning of the Initialize step
    return stack.Initialize.Add(defaultBucket, middleware.Before)
}

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    // handle error
}

client := s3.NewFromConfig(cfg)

object, err := client.GetObject(context.TODO(), &s3.GetObjectInput{
    Key: aws.String("my-key"),
}, func(options *s3.Options) {
    // Register the defaultBucketMiddleware for this operation only
    options.APIOptions = append(options.APIOptions, registerDefaultBucketMiddleware)
})
```

Passing Metadata Down the Stack

In certain situations, you may find that you require two or more middleware to function in tandem by sharing information or state. You can use context.Context to pass this metadata by using middleware.WithStackValue. `middleware.WithStackValue` attaches the given key-value pair to the provided context, and safely limits the scope to the currently executing stack. These stack-scoped values can be retrieved from a context using middleware.GetStackValue and providing the key used to stored the corresponding value. Keys must be comparable, and you must define your own types as context keys to avoid collisions. The following examples shows how two middleware can use `context.Context` to pass information down the stack.

```
import "context"
import "github.com/aws/smithy-go/middleware"

// ...

type customKey struct {}
```

```
func GetCustomKey(ctx context.Context) (v string) {
    v, _ = middleware.GetStackValue(ctx, customKey{}).(string)
    return v
}

func SetCustomKey(ctx context.Context, value string) context.Context {
    return middleware.WithStackValue(ctx, customKey{}, value)
}

// ...

var customInitalize = middleware.InitializeMiddlewareFunc("customInitialize", func(
    ctx context.Context, in middleware.InitializeInput, next
 middleware.InitializeHandler,
) (
    out middleware.InitializeOutput, metadata middleware.Metadata, err error,
) {
    ctx = SetCustomKey(ctx, "my-custom-value")

    return next.HandleInitialize(ctx, in)
})

var customBuild = middleware.BuildMiddlewareFunc("customBuild", func(
    ctx context.Context, in middleware.BuildInput, next middleware.BuildHandler,
) (
    out middleware.BuildOutput, metadata middleware.Metadata, err error,
) {
    customValue := GetCustomKey(ctx)

    // use customValue

    return next.HandleBuild(ctx, in)
})
```

Metadata Provided by the SDK

The AWS SDK for Go provides several metadata values that can be retrieved from the provided context. These values can be used to enable more dynamic middleware that modifies its behavior based on the executing service, operation, or target region. A few of the available keys are provided in the table below:

Key	Retriever	Description
ServiceID	GetServiceID	Retrieve the service identifier for the executing stack. This can be compared to the service client package's `ServiceID` constant.
OperationName	GetOperationName	Retrieve the operation name for the executing stack.
Logger	GetLogger	Retrieve the logger that can be used for logging message from the middleware.

Passing Metadata Up the Stack

You can pass metadata up through the stack by adding metadata key and value pairs using the middleware.Metadata. Each middleware step returns an output structure, metadata, and an error. Your custom middleware must return the metadata received from calling the next handler in the step. This ensures that metadata added by downstream middleware propagates to the application invoking the service operation. The resulting metadata is accessible to the invoking application by either the operation's output shape via the `ResultMetadata` structure member.

The following examples shows how a custom middleware can add metadata that is returned as part of the operation output.

```
import "context"
import "github.com/aws/aws-sdk-go-v2/service/s3"
import "github.com/aws/smithy-go/middleware"

// ...

type customKey struct{}

func GetCustomKey(metadata middleware.Metadata) (v string) {
    v, _ = metadata.Get(customKey{}).(string)
    return v
}
```

```
func SetCustomKey(metadata *middleware.Metadata, value string) {
    metadata.Set(customKey{}, value)
}

// ...

var customInitalize = middleware.InitializeMiddlewareFunc("customInitialize", func (
    ctx context.Context, in middleware.InitializeInput, next
 middleware.InitializeHandler,
) (
    out middleware.InitializeOutput, metadata middleware.Metadata, err error,
) {
    out, metadata, err = next.HandleInitialize(ctx, in)
    if err != nil {
        return out, metadata, err
    }

    SetCustomKey(&metadata, "my-custom-value")

    return out, metadata, nil
})

// ...

client := s3.NewFromConfig(cfg, func (options *s3.Options) {
    options.APIOptions = append(options.APIOptions, func(stack *middleware.Stack) error
 {
        return stack.Initialize.Add(customInitalize, middleware.After)
    })
})

out, err := client.GetObject(context.TODO(), &s3.GetObjectInput{
    // input parameters
})
if err != nil {
    // handle error
}

customValue := GetCustomKey(out.ResponseMetadata)
```

Frequently Asked Questions

How do I configure my SDK's HTTP client? Are there any guidelines or best practices?

We are unable to provide guidance to customers on how to configure their HTTP workflow in a manner that is most effective for their particular workload. The answer to this is the product of a multivariate equation, with input factors including but not limited to:

- the network footprint of the application (TPS, throughput, etc.)
- the services being used
- the compute characteristics of the deployment
- the geographical nature of the deployment
- the desired application behavior or needs of the application itself (SLAs, timings, etc.)

How should I configure operation timeouts?

Much like the previous question, it depends. Elements to consider here include the following:

- All of the above factors concerning HTTP client config
- Your own application timing or SLA constraints (e.g. if you yourself serve traffic to other consumers)

The answer to this question should almost NEVER be based on pure empirical observation of upstream behavior - e.g. "I made 1000 calls to this operation, it took at most 5 seconds so I will set the timeout based on that with a safety factor of 2x to 10 seconds". Environment conditions can change, services can temporarily degrade, and these types of assumptions can become wrong without warning.

Requests made by the SDK are timing out or taking too long, how do I fix this?

We are unable to assist with extended or timed-out operation calls due to extended time spent on the wire. "Wire time" in the SDK is defined as any of the following:

- Time spent in an SDK client's `HTTPClient.Do()` method
- Time spent in `Read()`s on an HTTP response body that has been forwarded to the caller (e.g. `GetObject`)

If you are experiencing issues due to operation latency or timeouts, your first course of action should be to obtain telemetry of the SDK operation lifecycle to determine the timing breakdown between time spent on the wire and the surrounding overhead of the operation. See the guide on timing SDK operations, which contains a reusable code snippet that can achieve this.

How do I fix a `read: connection reset` error?

The SDK retries any errors matching the `connection reset` pattern by default. This will cover error handling for most operations, where the operation's HTTP response is fully consumed and deserialized into its modeled result type.

However, this error can still occur in a context **outside** of the retry loop: certain service operations directly forward the API's HTTP response body to the caller to be consumed from the wire directly via `io.ReadCloser` (e.g. `GetObject`'s object payload). You may encounter this error when performing a `Read` on the response body.

This error indicates that your host, the service or any intermediary party (e.g. NAT gateways, proxies, load balancers) closed the connection while attempting to read the response.

This can occur for several reasons:

- You did not consume the response body for some time after the response itself was received (after the service operation was called). **We recommend you consume the HTTP response body as soon as possible for these types of operations.**
- You did not close a previously-received response body. This can cause connection resets on certain platforms. **You MUST close any `io.ReadCloser` instances provided in an operation's response, regardless of whether you consume its contents.**

Beyond that, try running a `tcpdump` for an affected connection at the edge of your network (e.g. after any proxies that you control). If you see that the AWS endpoint seems to be sending a TCP RST, you should use the AWS support console to open a case against the offending service. Be prepared to provide request IDs and specific timestamps of when the issue occured.

Why am I getting "invalid signature" errors when using an HTTP proxy with the SDK?

The signature algorithm for AWS services (generally sigv4) is tied to the serialized request's headers, more specifically most headers prefixed with `X-`. Proxies are prone to modifying the outgoing request by adding additional forwarding information (often via an `X-Forwarded-For` header) which effectively breaks the signature that the SDK calculated.

If you're using an HTTP proxy and experiencing signature errors, you should work to capture the request **as it appears outgoing from the proxy** and determine whether it is different.

Timing SDK operations

When debugging timeout/latency issues in the SDK, it is critical to identify the components of the operation lifecycle which are taking more time to execute than expected. As a starting point, you will generally need to inspect the timing breakdown between the overall operation call and the HTTP call itself.

The following sample program implements a basic instrumentation probe in terms of `smithy-go` middleware for SQS clients and demonstrates how it is used. The probe emits the following information for each operation call:

- AWS request ID
- service ID
- operation name
- operation invocation time
- http call time

Each emitted message is prefixed with a unique (to a single operation) "invocation ID" which is set at the beginning of the handler stack.

The entry point for instrumentation is exposed as `WithOperationTiming`, which is parameterized to accept a message handling function which will receive instrumentation "events" as formatted strings. `PrintfMSGHandler` is provided as a convenience which will simply dump messages to stdout.

The service used here is interchangeable - ALL service client options accept `APIOptions` and an `HTTPClient` as configuration. For example, `WithOperationTiming` could instead be declared as:

```
func WithOperationTiming(msgHandler func(string)) func(*s3.Options)
func WithOperationTiming(msgHandler func(string)) func(*dynamodb.Options)
// etc.
```

If you change it, be sure to change the signature of the function it returns as well.

```
import (
    "context"
    "fmt"
    "log"
    "net/http"
    "sync"
    "time"

    awsmiddleware "github.com/aws/aws-sdk-go-v2/aws/middleware"
    awshttp "github.com/aws/aws-sdk-go-v2/aws/transport/http"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/sqs"
    "github.com/aws/smithy-go/middleware"
    smithyrand "github.com/aws/smithy-go/rand"
)

// WithOperationTiming instruments an SQS client to dump timing information for
// the following spans:
//   - overall operation time
//   - HTTPClient call time
//
// This instrumentation will also emit the request ID, service name, and
// operation name for each invocation.
//
// Accepts a message "handler" which is invoked with formatted messages to be
// handled externally, you can use the declared PrintfMSGHandler to simply dump
// these values to stdout.
func WithOperationTiming(msgHandler func(string)) func(*sqs.Options) {
    return func(o *sqs.Options) {
        o.APIOptions = append(o.APIOptions, addTimingMiddlewares(msgHandler))
        o.HTTPClient = &timedHTTPClient{
            client:     awshttp.NewBuildableClient(),
            msgHandler: msgHandler,
        }
    }
}
```

```
// PrintfMSGHandler writes messages to stdout.
func PrintfMSGHandler(msg string) {
    fmt.Printf("%s\n", msg)
}

Unit Testing with the AWS SDK for Go v2

When using the SDK in your application, you'll want to mock out the SDK for your application's unit test. Mocking out the SDK allows your test to be focused on what you want to test, not the internals of the SDK.

To support mocking, use Go interfaces instead of concrete service client, paginators, and waiter types, such as `s3.Client`. This allows your application to use patterns like dependency injection to test your application logic.

Mocking Client Operations

In this example, `S3GetObjectAPI` is an interface that defines the set of Amazon S3 API operations required by the `GetObjectFromS3` function. `S3GetObjectAPI` is satisfied by the Amazon S3 client's GetObject method.

```
import "context"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

type S3GetObjectAPI interface {
    GetObject(ctx context.Context, params *s3.GetObjectInput,
 optFns ...func(*s3.Options)) (*s3.GetObjectOutput, error)
}

func GetObjectFromS3(ctx context.Context, api S3GetObjectAPI, bucket, key string)
 ([]byte, error) {
    object, err := api.GetObject(ctx, &s3.GetObjectInput{
        Bucket: &bucket,
        Key:    &key,
    })
    if err != nil {
        return nil, err
    }
    defer object.Body.Close()

    return ioutil.ReadAll(object.Body)
}
```

To test the `GetObjectFromS3` function, use the `mockGetObjectAPI` to satisfy the `S3GetObjectAPI` interface definition. Then use the `mockGetObjectAPI` type to mock output and error responses returned from the service client.

```
import "testing"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

type mockGetObjectAPI func(ctx context.Context, params *s3.GetObjectInput,
 optFns ...func(*s3.Options)) (*s3.GetObjectOutput, error)

func (m mockGetObjectAPI) GetObject(ctx context.Context, params *s3.GetObjectInput,
 optFns ...func(*s3.Options)) (*s3.GetObjectOutput, error) {
    return m(ctx, params, optFns...)
}

func TestGetObjectFromS3(t *testing.T) {
    cases := []struct {
        client func(t *testing.T) S3GetObjectAPI
        bucket string
        key string
        expect []byte
    }{
        {
            client: func(t *testing.T) S3GetObjectAPI {
                return mockGetObjectAPI(func(ctx context.Context, params
 *s3.GetObjectInput, optFns ...func(*s3.Options)) (*s3.GetObjectOutput, error) {
                    t.Helper()
                    if params.Bucket == nil {
                        t.Fatal("expect bucket to not be nil")
                    }
                    if e, a := "fooBucket", *params.Bucket; e != a {
                        t.Errorf("expect %v, got %v", e, a)
                    }
                    if params.Key == nil {
                        t.Fatal("expect key to not be nil")
                    }
                    if e, a := "barKey", *params.Key; e != a {
                        t.Errorf("expect %v, got %v", e, a)
                    }

                    return &s3.GetObjectOutput{
```

```
                        Body: ioutil.NopCloser(bytes.NewReader([]byte("this is the body
 foo bar baz"))),
                    }, nil
                })
            },
            bucket: "amzn-s3-demo-bucket>",
            key:    "barKey",
            expect: []byte("this is the body foo bar baz"),
        },
    }

    for i, tt := range cases {
        t.Run(strconv.Itoa(i), func(t *testing.T) {
            ctx := context.TODO()
            content, err := GetObjectFromS3(ctx, tt.client(t), tt.bucket, tt.key)
            if err != nil {
                t.Fatalf("expect no error, got %v", err)
            }
            if e, a := tt.expect, content; bytes.Compare(e, a) != 0 {
                t.Errorf("expect %v, got %v", e, a)
            }
        })
    }
}
```

Mocking Paginators

Similar to service clients, paginators can be mocked by defining a Go interface for the paginator. That interface would be used by your application's code. This allows the SDK's implementation to be used when your application is running, and a mocked implementation for testing.

In the following example, `ListObjectsV2Pager` is an interface that defines the behaviors for the Amazon S3 ListObjectsV2Paginator required by `CountObjects` function.

```
import "context"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

type ListObjectsV2Pager interface {
    HasMorePages() bool
    NextPage(context.Context, ...func(*s3.Options)) (*s3.ListObjectsV2Output, error)
```

```
}

func CountObjects(ctx context.Context, pager ListObjectsV2Pager) (count int, err error)
 {
    for pager.HasMorePages() {
        var output *s3.ListObjectsV2Output
        output, err = pager.NextPage(ctx)
        if err != nil {
            return count, err
        }
        count += int(output.KeyCount)
    }
    return count, nil
}
```

To test `CountObjects`, create the `mockListObjectsV2Pager` type to satisfy the `ListObjectsV2Pager` interface definition. Then use `mockListObjectsV2Pager` to replicate the paging behavior of output and error responses from the service operation paginator.

```
import "context"
import  "fmt"
import "testing"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

type mockListObjectsV2Pager struct {
    PageNum int
    Pages   []*s3.ListObjectsV2Output
}

func (m *mockListObjectsV2Pager) HasMorePages() bool {
    return m.PageNum < len(m.Pages)
}

func (m *mockListObjectsV2Pager) NextPage(ctx context.Context, f ...func(*s3.Options))
 (output *s3.ListObjectsV2Output, err error) {
    if m.PageNum >= len(m.Pages) {
        return nil, fmt.Errorf("no more pages")
    }
    output = m.Pages[m.PageNum]
    m.PageNum++
    return output, nil
```

```
}

func TestCountObjects(t *testing.T) {
    pager := &mockListObjectsV2Pager{
        Pages: []*s3.ListObjectsV2Output{
            {
                KeyCount: 5,
            },
            {
                KeyCount: 10,
            },
            {
                KeyCount: 15,
            },
        },
    }
    objects, err := CountObjects(context.TODO(), pager)
    if err != nil {
        t.Fatalf("expect no error, got %v", err)
    }
    if expect, actual := 30, objects; expect != actual {
        t.Errorf("expect %v, got %v", expect, actual)
    }
}
```

SDK for Go V2 code examples

The code examples in this topic show you how to use the AWS SDK for Go V2 with AWS.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Some services contain additional example categories that show how to leverage libraries or functions specific to the service.

Services

- API Gateway examples using SDK for Go V2
- Aurora examples using SDK for Go V2
- Amazon Bedrock examples using SDK for Go V2
- Amazon Bedrock Runtime examples using SDK for Go V2
- AWS CloudFormation examples using SDK for Go V2
- CloudWatch Logs examples using SDK for Go V2
- Amazon Cognito Identity Provider examples using SDK for Go V2
- Amazon DocumentDB examples using SDK for Go V2
- DynamoDB examples using SDK for Go V2
- IAM examples using SDK for Go V2
- Kinesis examples using SDK for Go V2
- Lambda examples using SDK for Go V2
- Amazon MSK examples using SDK for Go V2
- Partner Central examples using SDK for Go V2
- Amazon RDS examples using SDK for Go V2
- Amazon Redshift examples using SDK for Go V2

- Amazon S3 examples using SDK for Go V2
- Amazon SNS examples using SDK for Go V2
- Amazon SQS examples using SDK for Go V2

API Gateway examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with API Gateway.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Build and test a serverless application

The following code example shows how to build and test a serverless application using API Gateway with Lambda and DynamoDB

SDK for Go V2

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Go SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB

- Lambda

Aurora examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Aurora.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Aurora

The following code examples show how to get started using Aurora.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/rds"
)
```

```
// main uses the AWS SDK for Go V2 to create an Amazon Aurora client and list up to
 20
// DB clusters in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 auroraClient := rds.NewFromConfig(sdkConfig)
 const maxClusters = 20
 fmt.Printf("Let's list up to %v DB clusters.\n", maxClusters)
 output, err := auroraClient.DescribeDBClusters(
  ctx, &rds.DescribeDBClustersInput{MaxRecords: aws.Int32(maxClusters)})
 if err != nil {
  fmt.Printf("Couldn't list DB clusters: %v\n", err)
  return
 }
 if len(output.DBClusters) == 0 {
  fmt.Println("No DB clusters found.")
 } else {
  for _, cluster := range output.DBClusters {
   fmt.Printf("DB cluster %v has database %v.\n", *cluster.DBClusterIdentifier,
    *cluster.DatabaseName)
  }
 }
}
```

- For API details, see DescribeDBClusters in *AWS SDK for Go API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.
- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
import (
 "aurora/actions"
 "context"
 "fmt"
 "log"
 "slices"
 "sort"
 "strconv"
 "strings"
 "time"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/rds"
 "github.com/aws/aws-sdk-go-v2/service/rds/types"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/demotools"
 "github.com/google/uuid"
)
```

```
// GetStartedClusters is an interactive example that shows you how to use the AWS
 SDK for Go
// with Amazon Aurora to do the following:
//
// 1. Create a custom DB cluster parameter group and set parameter values.
// 2. Create an Aurora DB cluster that is configured to use the parameter group.
// 3. Create a DB instance in the DB cluster that contains a database.
// 4. Take a snapshot of the DB cluster.
// 5. Delete the DB instance, DB cluster, and parameter group.

Amazon Bedrock examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon Bedrock.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Bedrock

The following code examples show how to get started using Amazon Bedrock.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"

 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/bedrock"
)

const region = "us-east-1"

// main uses the AWS SDK for Go (v2) to create an Amazon Bedrock client and
// list the available foundation models in your account and the chosen region.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx, config.WithRegion(region))
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
```

```
  fmt.Println(err)
  return
 }
 bedrockClient := bedrock.NewFromConfig(sdkConfig)
 result, err := bedrockClient.ListFoundationModels(ctx,
 &bedrock.ListFoundationModelsInput{})
 if err != nil {
  fmt.Printf("Couldn't list foundation models. Here's why: %v\n", err)
  return
 }
 if len(result.ModelSummaries) == 0 {
  fmt.Println("There are no foundation models.")
 }
 for _, modelSummary := range result.ModelSummaries {
  fmt.Println(*modelSummary.ModelId)
 }
}
```

- For API details, see ListFoundationModels in *AWS SDK for Go API Reference*.

Topics

Actions

`ListFoundationModels`

The following code example shows how to use `ListFoundationModels`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

List the available Bedrock foundation models.

```
import (
 "context"
 "log"

 "github.com/aws/aws-sdk-go-v2/service/bedrock"
 "github.com/aws/aws-sdk-go-v2/service/bedrock/types"
)

// FoundationModelWrapper encapsulates Amazon Bedrock actions used in the examples.
// It contains a Bedrock service client that is used to perform foundation model
 actions.
type FoundationModelWrapper struct {
 BedrockClient *bedrock.Client
}

// ListPolicies lists Bedrock foundation models that you can use.
func (wrapper FoundationModelWrapper) ListFoundationModels(ctx context.Context)
 ([]types.FoundationModelSummary, error) {

 var models []types.FoundationModelSummary

 result, err := wrapper.BedrockClient.ListFoundationModels(ctx,
 &bedrock.ListFoundationModelsInput{})

 if err != nil {
  log.Printf("Couldn't list foundation models. Here's why: %v\n", err)
 } else {
  models = result.ModelSummaries
 }
 return models, err
}
```

- For API details, see ListFoundationModels in *AWS SDK for Go API Reference*.

Amazon Bedrock Runtime examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon Bedrock Runtime.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Bedrock

The following code examples show how to get started using Amazon Bedrock.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "encoding/json"
 "flag"
 "fmt"
 "log"
 "os"
 "strings"

 var converseInput = bedrockruntime.ConverseInput{
  ModelId:  aws.String(modelId),
  Messages: []types.Message{message},
 }
 response, err := wrapper.BedrockRuntimeClient.Converse(ctx, &converseInput)
 if err != nil {
  ProcessError(err, modelId)
 }

 responseText, _ := response.Output.(*types.ConverseOutputMemberMessage)
 responseContentBlock := responseText.Value.Content[0]
 text, _ := responseContentBlock.(*types.ContentBlockMemberText)
 return text.Value, nil

}
```

- For API details, see Converse in *AWS SDK for Go API Reference*.

InvokeModel

The following code example shows how to send a text message to Anthropic Claude, using the Invoke Model API.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Invoke the Anthropic Claude 2 foundation model to generate text.

```
import (
 "context"
 "encoding/json"
 "log"
 "strings"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/bedrockruntime"
)

// InvokeModelWrapper encapsulates Amazon Bedrock actions used in the examples.
// It contains a Bedrock Runtime client that is used to invoke foundation models.
type InvokeModelWrapper struct {
 BedrockRuntimeClient *bedrockruntime.Client
}

// Each model provider has their own individual request and response formats.
// For the format, ranges, and default values for Anthropic Claude, refer to:
// https://docs.aws.amazon.com/bedrock/latest/userguide/model-parameters-claude.html

type ClaudeRequest struct {
 Prompt            string   `json:"prompt"`
 MaxTokensToSample int      `json:"max_tokens_to_sample"`
 Temperature       float64  `json:"temperature,omitempty"`
 StopSequences     []string `json:"stop_sequences,omitempty"`
}

type ClaudeResponse struct {
 Completion string `json:"completion"`
}
```

```
// Invokes Anthropic Claude on Amazon Bedrock to run an inference using the input
// provided in the request body.
func (wrapper InvokeModelWrapper) InvokeClaude(ctx context.Context, prompt string)
 (string, error) {
 modelId := "anthropic.claude-v2"

 // Anthropic Claude requires enclosing the prompt as follows:
 enclosedPrompt := "Human: " + prompt + "\n\nAssistant:"

 body, err := json.Marshal(ClaudeRequest{
  Prompt:            enclosedPrompt,
  MaxTokensToSample: 200,
  Temperature:       0.5,
  StopSequences:     []string{"\n\nHuman:"},
 })

 if err != nil {
  log.Fatal("failed to marshal", err)
 }

 output, err := wrapper.BedrockRuntimeClient.InvokeModel(ctx,
 &bedrockruntime.InvokeModelInput{

Actions

`StartLiveTail`

The following code example shows how to use `StartLiveTail`.

SDK for Go V2

Include the required files.

```
import (
 "context"
 "log"
 "time"

 "github.com/aws/aws-sdk-go-v2/config"
```

```
 "github.com/aws/aws-sdk-go-v2/service/cloudwatchlogs"
 "github.com/aws/aws-sdk-go-v2/service/cloudwatchlogs/types"
)
```

Handle the events from the Live Tail session.

```
func handleEventStreamAsync(stream *cloudwatchlogs.StartLiveTailEventStream) {
 eventsChan := stream.Events()
 for {
  event := <-eventsChan
  switch e := event.(type) {
  case *types.StartLiveTailResponseStreamMemberSessionStart:
   log.Println("Received SessionStart event")
  case *types.StartLiveTailResponseStreamMemberSessionUpdate:
   for _, logEvent := range e.Value.SessionResults {
    log.Println(*logEvent.Message)
   }
  default:
   // Handle on-stream exceptions
   if err := stream.Err(); err != nil {
    log.Fatalf("Error occured during streaming: %v", err)
   } else if event == nil {
    log.Println("Stream is Closed")
    return
   } else {
    log.Fatalf("Unknown event type: %T", e)
   }
  }
 }
}
```

Start the Live Tail session.

```
 cfg, err := config.LoadDefaultConfig(context.TODO())
 if err != nil {
  panic("configuration error, " + err.Error())
 }
 client := cloudwatchlogs.NewFromConfig(cfg)

 request := &cloudwatchlogs.StartLiveTailInput{
  LogGroupIdentifiers:   logGroupIdentifiers,
```

```
 LogStreamNames:        logStreamNames,
 LogEventFilterPattern: logEventFilterPattern,
}

response, err := client.StartLiveTail(context.TODO(), request)
// Handle pre-stream Exceptions
if err != nil {
 log.Fatalf("Failed to start streaming: %v", err)
}

// Start a Goroutine to handle events over stream
stream := response.GetStream()
go handleEventStreamAsync(stream)
```

Stop the Live Tail session after a period of time has elapsed.

```
// Close the stream (which ends the session) after a timeout
time.Sleep(10 * time.Second)
stream.Close()
log.Println("Event stream closed")
```

- For API details, see StartLiveTail in *AWS SDK for Go API Reference*.

Amazon Cognito Identity Provider examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon Cognito Identity Provider.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Cognito

The following code examples show how to get started using Amazon Cognito.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/cognitoidentityprovider"
 "github.com/aws/aws-sdk-go-v2/service/cognitoidentityprovider/types"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Notification Service
// (Amazon SNS) client and list the topics in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 cognitoClient := cognitoidentityprovider.NewFromConfig(sdkConfig)
 fmt.Println("Let's list the user pools for your account.")
 var pools []types.UserPoolDescriptionType
 paginator := cognitoidentityprovider.NewListUserPoolsPaginator(
```

```
 cognitoClient, &cognitoidentityprovider.ListUserPoolsInput{MaxResults:
aws.Int32(10)})
for paginator.HasMorePages() {
 output, err := paginator.NextPage(ctx)
 if err != nil {
  log.Printf("Couldn't get user pools. Here's why: %v\n", err)
 } else {
  pools = append(pools, output.UserPools...)
 }
}
if len(pools) == 0 {
 fmt.Println("You don't have any user pools!")
} else {
 for _, pool := range pools {
  fmt.Printf("\t%v: %v\n", *pool.Name, *pool.Id)
 }
}
}
```

 if err != nil {
  log.Printf("Couldn't update user pool %v. Here's why: %v\n", userPoolId, err)
 }
 return err
}
```

- For API details, see UpdateUserPool in *AWS SDK for Go API Reference*.

Scenarios

Automatically confirm known users with a Lambda function

The following code example shows how to automatically confirm known Amazon Cognito users with a Lambda function.

- Configure a user pool to call a Lambda function for the `PreSignUp` trigger.
- Sign up a user with Amazon Cognito.
- The Lambda function scans a DynamoDB table and automatically confirms known users.
- Sign in as the new user, then clean up resources.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Automatically migrate known users with a Lambda function

The following code example shows how to automatically migrate known Amazon Cognito users with a Lambda function.

- Configure a user pool to call a Lambda function for the `MigrateUser` trigger.
- Sign in to Amazon Cognito with a username and email that is not in the user pool.
- The Lambda function scans a DynamoDB table and automatically migrates known users to the user pool.
- Perform the forgot password flow to reset the password for the migrated user.
- Sign in as the new user, then clean up resources.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

Write custom activity data with a Lambda function after Amazon Cognito user authentication

The following code example shows how to write custom activity data with a Lambda function after Amazon Cognito user authentication.

- Use administrator functions to add a user to a user pool.
- Configure a user pool to call a Lambda function for the `PostAuthentication` trigger.
- Sign the new user in to Amazon Cognito.

- The Lambda function writes custom information to CloudWatch Logs and to an DynamoDB table.
- Get and display custom data from the DynamoDB table, then clean up resources.

SDK for Go V2

Serverless examples

Invoke a Lambda function from a Amazon DocumentDB trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a DocumentDB change stream. The function retrieves the DocumentDB payload and logs the record contents.

SDK for Go V2

> **Note**

> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a Amazon DocumentDB event with Lambda using Go.

```
package main

import (
 "context"
 "encoding/json"
 "fmt"
```

```
 "github.com/aws/aws-lambda-go/lambda"
)

type Event struct {
 Events []Record `json:"events"`
}

type Record struct {
 Event struct {
  OperationType string `json:"operationType"`
  NS            struct {
   DB   string `json:"db"`
   Coll string `json:"coll"`
  } `json:"ns"`
  FullDocument interface{} `json:"fullDocument"`
 } `json:"event"`
}

func main() {
 lambda.Start(handler)
}

func handler(ctx context.Context, event Event) (string, error) {
 fmt.Println("Loading function")
 for _, record := range event.Events {
  logDocumentDBEvent(record)
 }

 return "OK", nil
}

func logDocumentDBEvent(record Record) {
 fmt.Printf("Operation type: %s\n", record.Event.OperationType)
 fmt.Printf("db: %s\n", record.Event.NS.DB)
 fmt.Printf("collection: %s\n", record.Event.NS.Coll)
 docBytes, _ := json.MarshalIndent(record.Event.FullDocument, "", "  ")
 fmt.Printf("Full document: %s\n", string(docBytes))
}
```

DynamoDB examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with DynamoDB.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

Basics

Learn the basics

The following code example shows how to:

- Create a table that can hold movie data.
- Put, get, and update a single movie in the table.
- Write movie data to the table from a sample JSON file.
- Query for movies that were released in a given year.
- Scan for movies that were released in a range of years.
- Delete a movie from the table, then delete the table.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario to create the table and perform actions on it.

```
import (
 "context"
 "fmt"
 "log"
 "strings"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/demotools"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/dynamodb/actions"
)

// RunMovieScenario is an interactive example that shows you how to use the AWS SDK
 for Go
// to create and use an Amazon DynamoDB table that stores data about movies.
//
//  1. Create a table that can hold movie data.
//  2. Put, get, and update a single movie in the table.
//  3. Write movie data to the table from a sample JSON file.
//  4. Query for movies that were released in a given year.
//  5. Scan for movies that were released in a range of years.
//  6. Delete a movie from the table.
//  7. Delete the table.
//
// This example creates a DynamoDB service client from the specified sdkConfig so
 that
// you can replace it with a mocked or stubbed config for unit testing.
//
// It uses a questioner from the `demotools` package to get input during the
 example.
// This package can be found in the ..\..\demotools folder of this repo.
//
```

```
// The specified movie sampler is used to get sample data from a URL that is loaded
// into the named table.

Actions

`BatchExecuteStatement`

The following code example shows how to use `BatchExecuteStatement`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Define a function receiver struct for the example.

```
import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// PartiQLRunner encapsulates the Amazon DynamoDB service actions used in the
// PartiQL examples. It contains a DynamoDB service client that is used to act on
 the
// specified table.
type PartiQLRunner struct {
 DynamoDbClient *dynamodb.Client
 TableName      string
}
```

Use batches of INSERT statements to add items.

```
// AddMovieBatch runs a batch of PartiQL INSERT statements to add multiple movies to
 the
// DynamoDB table.
func (runner PartiQLRunner) AddMovieBatch(ctx context.Context, movies []Movie) error
 {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year,
 movie.Info})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(fmt.Sprintf(
    "INSERT INTO \"%v\" VALUE {'title': ?, 'year': ?, 'info': ?}",
 runner.TableName)),
   Parameters: params,
  }
```

```
 }

 _, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 if err != nil {
  log.Printf("Couldn't insert a batch of items with PartiQL. Here's why: %v\n", err)
 }
 return err
}
```

Use batches of SELECT statements to get items.

```
// GetMovieBatch runs a batch of PartiQL SELECT statements to get multiple movies
 from
// the DynamoDB table by title and year.
func (runner PartiQLRunner) GetMovieBatch(ctx context.Context, movies []Movie)
 ([]Movie, error) {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(
    fmt.Sprintf("SELECT * FROM \"%v\" WHERE title=? AND year=?", runner.TableName)),
   Parameters: params,
  }
 }

 output, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 var outMovies []Movie
 if err != nil {
  log.Printf("Couldn't get a batch of items with PartiQL. Here's why: %v\n", err)
 } else {
```

```
  for _, response := range output.Responses {
   var movie Movie
   err = attributevalue.UnmarshalMap(response.Item, &movie)
   if err != nil {
    log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
   } else {
    outMovies = append(outMovies, movie)
   }
  }
 }
 return outMovies, err
}
```

Use batches of UPDATE statements to update items.

```
// UpdateMovieBatch runs a batch of PartiQL UPDATE statements to update the rating
 of
// multiple movies that already exist in the DynamoDB table.
func (runner PartiQLRunner) UpdateMovieBatch(ctx context.Context, movies []Movie,
 ratings []float64) error {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{ratings[index],
 movie.Title, movie.Year})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(
    fmt.Sprintf("UPDATE \"%v\" SET info.rating=? WHERE title=? AND year=?",
 runner.TableName)),
   Parameters: params,
  }
 }

 _, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 if err != nil {
```

```
  log.Printf("Couldn't update the batch of movies. Here's why: %v\n", err)
 }
 return err
}
```

Use batches of DELETE statements to delete items.

```
// DeleteMovieBatch runs a batch of PartiQL DELETE statements to remove multiple
 movies
// from the DynamoDB table.
func (runner PartiQLRunner) DeleteMovieBatch(ctx context.Context, movies []Movie)
 error {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(
    fmt.Sprintf("DELETE FROM \"%v\" WHERE title=? AND year=?", runner.TableName)),
   Parameters: params,
  }
 }

 _, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 if err != nil {
  log.Printf("Couldn't delete the batch of movies. Here's why: %v\n", err)
 }
 return err
}
```

Define a Movie struct that is used in this example.

```
import (
 "archive/zip"
 "bytes"
 "encoding/json"
 "fmt"
 "io"
 "log"
 "net/http"

 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// Movie encapsulates data about a movie. Title and Year are the composite primary
 key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
 key,
// and Info is additional data.
type Movie struct {
 Title string                `dynamodbav:"title"`
 Year  int                   `dynamodbav:"year"`
 Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
 title, err := attributevalue.Marshal(movie.Title)
 if err != nil {
  panic(err)
 }
 year, err := attributevalue.Marshal(movie.Year)
 if err != nil {
  panic(err)
 }
 return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
 example.
func (movie Movie) String() string {
 return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
  movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

}

// DeleteMovie removes a movie from the DynamoDB table.
func (basics TableBasics) DeleteMovie(ctx context.Context, movie Movie) error {
 _, err := basics.DynamoDbClient.DeleteItem(ctx, &dynamodb.DeleteItemInput{
  TableName: aws.String(basics.TableName), Key: movie.GetKey(),
```

```
 })
 if err != nil {
  log.Printf("Couldn't delete %v from the table. Here's why: %v\n", movie.Title,
 err)
 }
 return err
}
```

Define a Movie struct that is used in this example.

```
import (
 "archive/zip"
 "bytes"
 "encoding/json"
 "fmt"
 "io"
 "log"
 "net/http"

 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// Movie encapsulates data about a movie. Title and Year are the composite primary
 key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
 key,
// and Info is additional data.
type Movie struct {
 Title string                 `dynamodbav:"title"`
 Year  int                    `dynamodbav:"year"`
 Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
 title, err := attributevalue.Marshal(movie.Title)
 if err != nil {
  panic(err)
```

```
 }
 year, err := attributevalue.Marshal(movie.Year)
 if err != nil {
  panic(err)
 }
 return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
 example.
func (movie Movie) String() string {
 return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
  movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

- For API details, see DeleteItem in *AWS SDK for Go API Reference*.

`DeleteTable`

The following code example shows how to use `DeleteTable`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "errors"

 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/expression"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
```

```
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// TableBasics encapsulates the Amazon DynamoDB service actions used in the
 examples.
// It contains a DynamoDB service client that is used to act on the specified table.
type TableBasics struct {
 DynamoDbClient *dynamodb.Client
 TableName      string
}

// DeleteTable deletes the DynamoDB table and all of its data.
func (basics TableBasics) DeleteTable(ctx context.Context) error {
 _, err := basics.DynamoDbClient.DeleteTable(ctx, &dynamodb.DeleteTableInput{
  TableName: aws.String(basics.TableName)})
 if err != nil {
  log.Printf("Couldn't delete table %v. Here's why: %v\n", basics.TableName, err)
 }
 return err
}
```

- For API details, see DeleteTable in *AWS SDK for Go API Reference*.

`DescribeTable`

The following code example shows how to use `DescribeTable`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
```

```
 "errors"
 "log"
 "time"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/expression"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// TableBasics encapsulates the Amazon DynamoDB service actions used in the
 examples.
// It contains a DynamoDB service client that is used to act on the specified table.
type TableBasics struct {
 DynamoDbClient *dynamodb.Client
 TableName      string
}

// TableExists determines whether a DynamoDB table exists.
func (basics TableBasics) TableExists(ctx context.Context) (bool, error) {
 exists := true
 _, err := basics.DynamoDbClient.DescribeTable(
  ctx, &dynamodb.DescribeTableInput{TableName: aws.String(basics.TableName)},
 )
 if err != nil {
  var notFoundEx *types.ResourceNotFoundException
  if errors.As(err, &notFoundEx) {
   log.Printf("Table %v does not exist.\n", basics.TableName)
   err = nil
  } else {
   log.Printf("Couldn't determine existence of table %v. Here's why: %v\n",
 basics.TableName, err)
  }
  exists = false
 }
 return exists, err
}
```

- For API details, see DescribeTable in *AWS SDK for Go API Reference*.

`ExecuteStatement`

The following code example shows how to use `ExecuteStatement`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Define a function receiver struct for the example.

```
import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// PartiQLRunner encapsulates the Amazon DynamoDB service actions used in the
// PartiQL examples. It contains a DynamoDB service client that is used to act on
 the
// specified table.
type PartiQLRunner struct {
 DynamoDbClient *dynamodb.Client
 TableName      string
}
```

Use an INSERT statement to add an item.

```
// AddMovie runs a PartiQL INSERT statement to add a movie to the DynamoDB table.
func (runner PartiQLRunner) AddMovie(ctx context.Context, movie Movie) error {
```

```
 params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year,
 movie.Info})
 if err != nil {
  panic(err)
 }
 _, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("INSERT INTO \"%v\" VALUE {'title': ?, 'year': ?, 'info': ?}",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't insert an item with PartiQL. Here's why: %v\n", err)
 }
 return err
}
```

Use a SELECT statement to get an item.

```
// GetMovie runs a PartiQL SELECT statement to get a movie from the DynamoDB table
 by
// title and year.
func (runner PartiQLRunner) GetMovie(ctx context.Context, title string, year int)
 (Movie, error) {
 var movie Movie
 params, err := attributevalue.MarshalList([]interface{}{title, year})
 if err != nil {
  panic(err)
 }
 response, err := runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("SELECT * FROM \"%v\" WHERE title=? AND year=?",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't get info about %v. Here's why: %v\n", title, err)
 } else {
```

```
  err = attributevalue.UnmarshalMap(response.Items[0], &movie)
  if err != nil {
   log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
  }
 }
 return movie, err
}
```

Use a SELECT statement to get a list of items and project the results.

```
// GetAllMovies runs a PartiQL SELECT statement to get all movies from the DynamoDB
 table.
// pageSize is not typically required and is used to show how to paginate the
 results.
// The results are projected to return only the title and rating of each movie.
func (runner PartiQLRunner) GetAllMovies(ctx context.Context, pageSize int32)
 ([]map[string]interface{}, error) {
 var output []map[string]interface{}
 var response *dynamodb.ExecuteStatementOutput
 var err error
 var nextToken *string
 for moreData := true; moreData; {
  response, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
   Statement: aws.String(
    fmt.Sprintf("SELECT title, info.rating FROM \"%v\"", runner.TableName)),
   Limit:     aws.Int32(pageSize),
   NextToken: nextToken,
  })
  if err != nil {
   log.Printf("Couldn't get movies. Here's why: %v\n", err)
   moreData = false
  } else {
   var pageOutput []map[string]interface{}
   err = attributevalue.UnmarshalListOfMaps(response.Items, &pageOutput)
   if err != nil {
    log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
   } else {
    log.Printf("Got a page of length %v.\n", len(response.Items))
    output = append(output, pageOutput...)
```

```
   }
   nextToken = response.NextToken
   moreData = nextToken != nil
  }
 }
 return output, err
}
```

Use an UPDATE statement to update an item.

```
// UpdateMovie runs a PartiQL UPDATE statement to update the rating of a movie that
// already exists in the DynamoDB table.
func (runner PartiQLRunner) UpdateMovie(ctx context.Context, movie Movie, rating
 float64) error {
 params, err := attributevalue.MarshalList([]interface{}{rating, movie.Title,
 movie.Year})
 if err != nil {
  panic(err)
 }
 _, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("UPDATE \"%v\" SET info.rating=? WHERE title=? AND year=?",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't update movie %v. Here's why: %v\n", movie.Title, err)
 }
 return err
}
```

Use a DELETE statement to delete an item.

```
// DeleteMovie runs a PartiQL DELETE statement to remove a movie from the DynamoDB
 table.
func (runner PartiQLRunner) DeleteMovie(ctx context.Context, movie Movie) error {
```

```
 params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year})
 if err != nil {
  panic(err)
 }
 _, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("DELETE FROM \"%v\" WHERE title=? AND year=?",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't delete %v from the table. Here's why: %v\n", movie.Title,
 err)
 }
 return err
}
```

Define a Movie struct that is used in this example.

```
import (
 "archive/zip"
 "bytes"
 "encoding/json"
 "fmt"
 "io"
 "log"
 "net/http"

 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// Movie encapsulates data about a movie. Title and Year are the composite primary
 key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
 key,
// and Info is additional data.
type Movie struct {
 Title string                `dynamodbav:"title"`
```

```
 Year  int                    `dynamodbav:"year"`
 Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
 title, err := attributevalue.Marshal(movie.Title)
 if err != nil {
  panic(err)
 }
 year, err := attributevalue.Marshal(movie.Year)
 if err != nil {
  panic(err)
 }
 return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
 example.
func (movie Movie) String() string {
 return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
  movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

- For API details, see ExecuteStatement in *AWS SDK for Go API Reference*.

`GetItem`

The following code example shows how to use `GetItem`.

SDK for Go V2

> **Note**

Scenarios

Query a table by using batches of PartiQL statements

The following code example shows how to:

- Get a batch of items by running multiple SELECT statements.
- Add a batch of items by running multiple INSERT statements.
- Update a batch of items by running multiple UPDATE statements.
- Delete a batch of items by running multiple DELETE statements.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run a scenario that creates a table and runs batches of PartiQL queries.

```
import (
 "context"
 "fmt"
 "log"
 "strings"
 "time"
```

```
 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/dynamodb/actions"
)

// RunPartiQLBatchScenario shows you how to use the AWS SDK for Go
// to run batches of PartiQL statements to query a table that stores data about
 movies.
//
//   - Use batches of PartiQL statements to add, get, update, and delete data for
//     individual movies.
//
// This example creates an Amazon DynamoDB service client from the specified
 sdkConfig so that
// you can replace it with a mocked or stubbed config for unit testing.
//
// This example creates and deletes a DynamoDB table to use during the scenario.

Query a table using PartiQL

The following code example shows how to:

- Get an item by running a SELECT statement.
- Add an item by running an INSERT statement.
- Update an item by running an UPDATE statement.
- Delete an item by running a DELETE statement.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run a scenario that creates a table and runs PartiQL queries.

```
import (
 "context"

Serverless examples

Invoke a Lambda function from a DynamoDB trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a DynamoDB stream. The function retrieves the DynamoDB payload and logs the record contents.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a DynamoDB event with Lambda using Go.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
package main

import (
 "context"
 "github.com/aws/aws-lambda-go/lambda"
 "github.com/aws/aws-lambda-go/events"
 "fmt"
)

func HandleRequest(ctx context.Context, event events.DynamoDBEvent) (*string, error)
 {
 if len(event.Records) == 0 {
  return nil, fmt.Errorf("received empty event")
 }

 for _, record := range event.Records {
   LogDynamoDBRecord(record)
```

```
 }

 message := fmt.Sprintf("Records processed: %d", len(event.Records))
 return &message, nil
}

func main() {
 lambda.Start(HandleRequest)
}

func LogDynamoDBRecord(record events.DynamoDBEventRecord){
 fmt.Println(record.EventID)
 fmt.Println(record.EventName)
 fmt.Printf("%+v\n", record.Change)
}
```

Reporting batch item failures for Lambda functions with a DynamoDB trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a DynamoDB stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Reporting DynamoDB batch item failures with Lambda using Go.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
package main

import (
 "context"
 "github.com/aws/aws-lambda-go/events"
 "github.com/aws/aws-lambda-go/lambda"
)
```

```
type BatchItemFailure struct {
 ItemIdentifier string `json:"ItemIdentifier"`
}

type BatchResult struct {
 BatchItemFailures []BatchItemFailure `json:"BatchItemFailures"`
}

func HandleRequest(ctx context.Context, event events.DynamoDBEvent) (*BatchResult,
 error) {
 var batchItemFailures []BatchItemFailure
 curRecordSequenceNumber := ""

 for _, record := range event.Records {
  // Process your record
  curRecordSequenceNumber = record.Change.SequenceNumber
 }

 if curRecordSequenceNumber != "" {
  batchItemFailures = append(batchItemFailures, BatchItemFailure{ItemIdentifier:
 curRecordSequenceNumber})
 }

 batchResult := BatchResult{
  BatchItemFailures: batchItemFailures,
 }

 return &batchResult, nil
}

func main() {
 lambda.Start(HandleRequest)
}
```

AWS community contributions

Build and test a serverless application

The following code example shows how to build and test a serverless application using API Gateway with Lambda and DynamoDB

SDK for Go V2

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Go SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda

IAM examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with IAM.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello IAM

The following code examples show how to get started using IAM.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/iam"
)

// main uses the AWS SDK for Go (v2) to create an AWS Identity and Access Management
 (IAM)
// client and list up to 10 policies in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 iamClient := iam.NewFromConfig(sdkConfig)
 const maxPols = 10
 fmt.Printf("Let's list up to %v policies for your account.\n", maxPols)
 result, err := iamClient.ListPolicies(ctx, &iam.ListPoliciesInput{
  MaxItems: aws.Int32(maxPols),
 })
 if err != nil {
  fmt.Printf("Couldn't list policies for your account. Here's why: %v\n", err)
  return
 }
 if len(result.Policies) == 0 {
  fmt.Println("You don't have any policies!")
 } else {
  for _, policy := range result.Policies {
   fmt.Printf("\t%v\n", *policy.PolicyName)
  }
 }
```

```
}
```

- For API details, see ListPolicies in *AWS SDK for Go API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to create a user and assume a role.

> **Warning**
>
> To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as AWS IAM Identity Center.

- Create a user with no permissions.
- Create a role that grants permission to list Amazon S3 buckets for the account.
- Add a policy to let the user assume the role.
- Assume the role and list S3 buckets using temporary credentials, then clean up resources.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

  - AttachRolePolicy
  - CreateAccessKey
  - CreatePolicy
  - CreateRole
  - CreateUser
  - DeleteAccessKey
  - DeletePolicy
  - DeleteRole
  - DeleteUser
  - DeleteUserPolicy
  - DetachRolePolicy
  - PutUserPolicy

Actions

`AttachRolePolicy`

The following code example shows how to use `AttachRolePolicy`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// RoleWrapper encapsulates AWS Identity and Access Management (IAM) role actions
// used in the examples.
// It contains an IAM service client that is used to perform role actions.
type RoleWrapper struct {
 IamClient *iam.Client
}

// AttachRolePolicy attaches a policy to a role.
func (wrapper RoleWrapper) AttachRolePolicy(ctx context.Context, policyArn string,
 roleName string) error {
 _, err := wrapper.IamClient.AttachRolePolicy(ctx, &iam.AttachRolePolicyInput{
  PolicyArn: aws.String(policyArn),
  RoleName:  aws.String(roleName),
 })
 if err != nil {
  log.Printf("Couldn't attach policy %v to role %v. Here's why: %v\n", policyArn,
 roleName, err)
 }
 return err
}
```

- For API details, see AttachRolePolicy in *AWS SDK for Go API Reference*.

`CreateAccessKey`

The following code example shows how to use `CreateAccessKey`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "errors"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
 "github.com/aws/smithy-go"
)

// UserWrapper encapsulates user actions used in the examples.
// It contains an IAM service client that is used to perform user actions.
type UserWrapper struct {
 IamClient *iam.Client
}

// CreateAccessKeyPair creates an access key for a user. The returned access key
 contains
// the ID and secret credentials needed to use the key.
func (wrapper UserWrapper) CreateAccessKeyPair(ctx context.Context, userName string)
 (*types.AccessKey, error) {
```

```
 var key *types.AccessKey
 result, err := wrapper.IamClient.CreateAccessKey(ctx, &iam.CreateAccessKeyInput{
  UserName: aws.String(userName)})
 if err != nil {
  log.Printf("Couldn't create access key pair for user %v. Here's why: %v\n",
 userName, err)
 } else {
  key = result.AccessKey
 }
 return key, err
}
```

- For API details, see CreateAccessKey in *AWS SDK for Go API Reference*.

`CreatePolicy`

The following code example shows how to use `CreatePolicy`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// PolicyWrapper encapsulates AWS Identity and Access Management (IAM) policy
 actions
// used in the examples.
```

```
// It contains an IAM service client that is used to perform policy actions.
type PolicyWrapper struct {
 IamClient *iam.Client
}

// PolicyDocument defines a policy document as a Go struct that can be serialized
// to JSON.
type PolicyDocument struct {
 Version   string
 Statement []PolicyStatement
}

// PolicyStatement defines a statement in a policy document.
type PolicyStatement struct {
 Effect    string
 Action    []string
 Principal map[string]string `json:",omitempty"`
 Resource  *string           `json:",omitempty"`
}

// CreatePolicy creates a policy that grants a list of actions to the specified
 resource.
// PolicyDocument shows how to work with a policy document as a data structure and
// serialize it to JSON by using Go's JSON marshaler.
func (wrapper PolicyWrapper) CreatePolicy(ctx context.Context, policyName string,
 actions []string,
 resourceArn string) (*types.Policy, error) {
 var policy *types.Policy
 policyDoc := PolicyDocument{
  Version: "2012-10-17"&TCX5-2025-waiver;,
  Statement: []PolicyStatement{{
   Effect:   "Allow",
   Action:   actions,
   Resource: aws.String(resourceArn),
  }},
 }
 policyBytes, err := json.Marshal(policyDoc)
 if err != nil {
  log.Printf("Couldn't create policy document for %v. Here's why: %v\n",
 resourceArn, err)
  return nil, err
 }
```

```
 result, err := wrapper.IamClient.CreatePolicy(ctx, &iam.CreatePolicyInput{
  PolicyDocument: aws.String(string(policyBytes)),
  PolicyName:     aws.String(policyName),
 })
 if err != nil {
  log.Printf("Couldn't create policy %v. Here's why: %v\n", policyName, err)
 } else {
  policy = result.Policy
 }
 return policy, err
}
```

- For API details, see CreatePolicy in *AWS SDK for Go API Reference*.

`CreateRole`

The following code example shows how to use `CreateRole`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// RoleWrapper encapsulates AWS Identity and Access Management (IAM) role actions
// used in the examples.
```

```
// It contains an IAM service client that is used to perform role actions.
type RoleWrapper struct {
 IamClient *iam.Client
}

// CreateRole creates a role that trusts a specified user. The trusted user can
 assume
// the role to acquire its permissions.
// PolicyDocument shows how to work with a policy document as a data structure and
// serialize it to JSON by using Go's JSON marshaler.
func (wrapper RoleWrapper) CreateRole(ctx context.Context, roleName string,
 trustedUserArn string) (*types.Role, error) {
 var role *types.Role
 trustPolicy := PolicyDocument{
  Version: "2012-10-17"&TCX5-2025-waiver;,
  Statement: []PolicyStatement{{
   Effect:    "Allow",
   Principal: map[string]string{"AWS": trustedUserArn},
   Action:    []string{"sts:AssumeRole"},
  }},
 }
 policyBytes, err := json.Marshal(trustPolicy)
 if err != nil {
  log.Printf("Couldn't create trust policy for %v. Here's why: %v\n",
 trustedUserArn, err)
  return nil, err
 }
 result, err := wrapper.IamClient.CreateRole(ctx, &iam.CreateRoleInput{
  AssumeRolePolicyDocument: aws.String(string(policyBytes)),
  RoleName:                 aws.String(roleName),
 })
 if err != nil {
  log.Printf("Couldn't create role %v. Here's why: %v\n", roleName, err)
 } else {
  role = result.Role
 }
 return role, err
}
```

- For API details, see CreateRole in *AWS SDK for Go API Reference*.

`CreateServiceLinkedRole`

The following code example shows how to use `CreateServiceLinkedRole`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// RoleWrapper encapsulates AWS Identity and Access Management (IAM) role actions
// used in the examples.
// It contains an IAM service client that is used to perform role actions.
type RoleWrapper struct {
 IamClient *iam.Client
}

// CreateServiceLinkedRole creates a service-linked role that is owned by the
 specified service.
func (wrapper RoleWrapper) CreateServiceLinkedRole(ctx context.Context, serviceName
 string, description string) (
 *types.Role, error) {
 var role *types.Role
 result, err := wrapper.IamClient.CreateServiceLinkedRole(ctx,
 &iam.CreateServiceLinkedRoleInput{
  AWSServiceName: aws.String(serviceName),
  Description:    aws.String(description),
 })
```

```
 if err != nil {
  log.Printf("Couldn't create service-linked role %v. Here's why: %v\n",
 serviceName, err)
 } else {
  role = result.Role
 }
 return role, err
}
```

- For API details, see CreateServiceLinkedRole in *AWS SDK for Go API Reference*.

`CreateUser`

The following code example shows how to use `CreateUser`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "errors"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
 "github.com/aws/smithy-go"
)

// UserWrapper encapsulates user actions used in the examples.
// It contains an IAM service client that is used to perform user actions.
type UserWrapper struct {
 IamClient *iam.Client
```

```
}

// CreateUser creates a new user with the specified name.
func (wrapper UserWrapper) CreateUser(ctx context.Context, userName string)
 (*types.User, error) {
 var user *types.User
 result, err := wrapper.IamClient.CreateUser(ctx, &iam.CreateUserInput{
  UserName: aws.String(userName),
 })
 if err != nil {
  log.Printf("Couldn't create user %v. Here's why: %v\n", userName, err)
 } else {
  user = result.User
 }
 return user, err
}
```

- For API details, see CreateUser in *AWS SDK for Go API Reference*.

`DeleteAccessKey`

The following code example shows how to use `DeleteAccessKey`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "errors"
 "log"
```

```

 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
 "github.com/aws/smithy-go"
)

// UserWrapper encapsulates user actions used in the examples.
// It contains an IAM service client that is used to perform user actions.
type UserWrapper struct {
 IamClient *iam.Client
}

// DeleteAccessKey deletes an access key from a user.
func (wrapper UserWrapper) DeleteAccessKey(ctx context.Context, userName string,
 keyId string) error {
 _, err := wrapper.IamClient.DeleteAccessKey(ctx, &iam.DeleteAccessKeyInput{
  AccessKeyId: aws.String(keyId),
  UserName:    aws.String(userName),
 })
 if err != nil {
  log.Printf("Couldn't delete access key %v. Here's why: %v\n", keyId, err)
 }
 return err
}
```

- For API details, see DeleteAccessKey in *AWS SDK for Go API Reference*.

`DeletePolicy`

The following code example shows how to use `DeletePolicy`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// PolicyWrapper encapsulates AWS Identity and Access Management (IAM) policy
 actions
// used in the examples.
// It contains an IAM service client that is used to perform policy actions.
type PolicyWrapper struct {
 IamClient *iam.Client
}

// DeletePolicy deletes a policy.
func (wrapper PolicyWrapper) DeletePolicy(ctx context.Context, policyArn string)
 error {
 _, err := wrapper.IamClient.DeletePolicy(ctx, &iam.DeletePolicyInput{
  PolicyArn: aws.String(policyArn),
 })
 if err != nil {
  log.Printf("Couldn't delete policy %v. Here's why: %v\n", policyArn, err)
 }
 return err
}
```

- For API details, see DeletePolicy in *AWS SDK for Go API Reference*.

`DeleteRole`

The following code example shows how to use `DeleteRole`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// RoleWrapper encapsulates AWS Identity and Access Management (IAM) role actions
// used in the examples.
// It contains an IAM service client that is used to perform role actions.
type RoleWrapper struct {
 IamClient *iam.Client
}

// DeleteRole deletes a role. All attached policies must be detached before a
// role can be deleted.
func (wrapper RoleWrapper) DeleteRole(ctx context.Context, roleName string) error {
 _, err := wrapper.IamClient.DeleteRole(ctx, &iam.DeleteRoleInput{
  RoleName: aws.String(roleName),
 })
 if err != nil {
  log.Printf("Couldn't delete role %v. Here's why: %v\n", roleName, err)
 }
 return err
}
```

- For API details, see DeleteRole in *AWS SDK for Go API Reference*.

`DeleteServiceLinkedRole`

The following code example shows how to use `DeleteServiceLinkedRole`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"

 "github.com/aws/aws-sdk-go-v2/service/iam/types"
 "github.com/aws/smithy-go"
)

// UserWrapper encapsulates user actions used in the examples.
```

```
// It contains an IAM service client that is used to perform user actions.
type UserWrapper struct {
 IamClient *iam.Client
}

// DeleteUserPolicy deletes an inline policy from a user.
func (wrapper UserWrapper) DeleteUserPolicy(ctx context.Context, userName string,
 policyName string) error {
 _, err := wrapper.IamClient.DeleteUserPolicy(ctx, &iam.DeleteUserPolicyInput{
  PolicyName: aws.String(policyName),
  UserName:   aws.String(userName),
 })
 if err != nil {
  log.Printf("Couldn't delete policy from user %v. Here's why: %v\n", userName, err)
 }
 return err
}
```

- For API details, see DeleteUserPolicy in *AWS SDK for Go API Reference*.

`DetachRolePolicy`

The following code example shows how to use `DetachRolePolicy`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"
```

```
 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// RoleWrapper encapsulates AWS Identity and Access Management (IAM) role actions
// used in the examples.
// It contains an IAM service client that is used to perform role actions.
type RoleWrapper struct {
 IamClient *iam.Client
}

// DetachRolePolicy detaches a policy from a role.
func (wrapper RoleWrapper) DetachRolePolicy(ctx context.Context, roleName string,
 policyArn string) error {
 _, err := wrapper.IamClient.DetachRolePolicy(ctx, &iam.DetachRolePolicyInput{
  PolicyArn: aws.String(policyArn),
  RoleName:  aws.String(roleName),
 })
 if err != nil {
  log.Printf("Couldn't detach policy from role %v. Here's why: %v\n", roleName, err)
 }
 return err
}
```

- For API details, see DetachRolePolicy in *AWS SDK for Go API Reference*.

`GetAccountPasswordPolicy`

The following code example shows how to use `GetAccountPasswordPolicy`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "log"

 "github.com/aws/aws-sdk-go-v2/service/iam"
 "github.com/aws/aws-sdk-go-v2/service/iam/types"
)

// AccountWrapper encapsulates AWS Identity and Access Management (IAM) account
 actions
// used in the examples.
// It contains an IAM service client that is used to perform account actions.
type AccountWrapper struct {
 IamClient *iam.Client
}

// GetAccountPasswordPolicy gets the account password policy for the current
 account.
// If no policy has been set, a NoSuchEntityException is error is returned.
func (wrapper AccountWrapper) GetAccountPasswordPolicy(ctx context.Context)
 (*types.PasswordPolicy, error) {
 var pwPolicy *types.PasswordPolicy
 result, err := wrapper.IamClient.GetAccountPasswordPolicy(ctx,
  &iam.GetAccountPasswordPolicyInput{})
 if err != nil {
  log.Printf("Couldn't get account password policy. Here's why: %v\n", err)
 } else {
  pwPolicy = result.PasswordPolicy
 }
 return pwPolicy, err
}
```

- For API details, see GetAccountPasswordPolicy in *AWS SDK for Go API Reference*.

`GetPolicy`

The following code example shows how to use `GetPolicy`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

  PolicyName:     aws.String(policyName),
  UserName:       aws.String(userName),
 })
 if err != nil {
  log.Printf("Couldn't create policy for user %v. Here's why: %v\n", userName, err)
 }
 return err
}
```

- For API details, see PutUserPolicy in *AWS SDK for Go API Reference*.

Kinesis examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Kinesis.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Serverless examples

Serverless examples

Invoke a Lambda function from a Kinesis trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a Kinesis stream. The function retrieves the Kinesis payload, decodes from Base64, and logs the record contents.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a Kinesis event with Lambda using Go.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
package main

import (
 "context"
 "log"

 "github.com/aws/aws-lambda-go/events"
 "github.com/aws/aws-lambda-go/lambda"
)

func handler(ctx context.Context, kinesisEvent events.KinesisEvent) error {
 if len(kinesisEvent.Records) == 0 {
  log.Printf("empty Kinesis event received")
  return nil
 }

 for _, record := range kinesisEvent.Records {
  log.Printf("processed Kinesis event with EventId: %v", record.EventID)
  recordDataBytes := record.Kinesis.Data
  recordDataText := string(recordDataBytes)
  log.Printf("record data: %v", recordDataText)
  // TODO: Do interesting work based on the new data
```

```
 }
 log.Printf("successfully processed %v records", len(kinesisEvent.Records))
 return nil
}

func main() {
 lambda.Start(handler)
}
```

Reporting batch item failures for Lambda functions with a Kinesis trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a Kinesis stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Reporting Kinesis batch item failures with Lambda using Go.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
package main

import (
 "context"
 "fmt"
 "github.com/aws/aws-lambda-go/events"
 "github.com/aws/aws-lambda-go/lambda"
)

func handler(ctx context.Context, kinesisEvent events.KinesisEvent)
 (map[string]interface{}, error) {
 batchItemFailures := []map[string]interface{}{}
```

```
 for _, record := range kinesisEvent.Records {
  curRecordSequenceNumber := ""

  // Process your record
  if /* Your record processing condition here */ {
   curRecordSequenceNumber = record.Kinesis.SequenceNumber
  }

  // Add a condition to check if the record processing failed
  if curRecordSequenceNumber != "" {
   batchItemFailures = append(batchItemFailures, map[string]interface{}
{"itemIdentifier": curRecordSequenceNumber})
  }
 }

 kinesisBatchResponse := map[string]interface{}{
  "batchItemFailures": batchItemFailures,
 }
 return kinesisBatchResponse, nil
}

func main() {
 lambda.Start(handler)
}
```

Lambda examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Lambda.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Lambda

The following code examples show how to get started using Lambda.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/lambda"
)

// main uses the AWS SDK for Go (v2) to create an AWS Lambda client and list up to
 10
// functions in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
```

```
 lambdaClient := lambda.NewFromConfig(sdkConfig)

 maxItems := 10
 fmt.Printf("Let's list up to %v functions for your account.\n", maxItems)
 result, err := lambdaClient.ListFunctions(ctx, &lambda.ListFunctionsInput{
  MaxItems: aws.Int32(int32(maxItems)),
 })
 if err != nil {
  fmt.Printf("Couldn't list functions for your account. Here's why: %v\n", err)
  return
 }
 if len(result.Functions) == 0 {
  fmt.Println("You don't have any functions!")
 } else {
  for _, function := range result.Functions {
   fmt.Printf("\t%v\n", *function.FunctionName)
  }
 }
}
```

- For API details, see ListFunctions in *AWS SDK for Go API Reference*.

- AWS community contributions

Basics

Learn the basics

The following code example shows how to:

- Create an IAM role and Lambda function, then upload handler code.
- Invoke the function with a single parameter and get results.

- Update the function code and configure with an environment variable.
- Invoke the function with new parameters and get results. Display the returned execution log.
- List the functions for your account, then clean up resources.

For more information, see Create a Lambda function with the console.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create an interactive scenario that shows you how to get started with Lambda functions.

Scenarios

Automatically confirm known users with a Lambda function

The following code example shows how to automatically confirm known Amazon Cognito users with a Lambda function.

- Configure a user pool to call a Lambda function for the `PreSignUp` trigger.
- Sign up a user with Amazon Cognito.
- The Lambda function scans a DynamoDB table and automatically confirms known users.
- Sign in as the new user, then clean up resources.

SDK for Go V2

Automatically migrate known users with a Lambda function

The following code example shows how to automatically migrate known Amazon Cognito users with a Lambda function.

- Configure a user pool to call a Lambda function for the `MigrateUser` trigger.

- Sign in to Amazon Cognito with a username and email that is not in the user pool.
- The Lambda function scans a DynamoDB table and automatically migrates known users to the user pool.
- Perform the forgot password flow to reset the password for the migrated user.
- Sign in as the new user, then clean up resources.

SDK for Go V2

Write custom activity data with a Lambda function after Amazon Cognito user authentication

The following code example shows how to write custom activity data with a Lambda function after Amazon Cognito user authentication.

- Use administrator functions to add a user to a user pool.
- Configure a user pool to call a Lambda function for the `PostAuthentication` trigger.
- Sign the new user in to Amazon Cognito.
- The Lambda function writes custom information to CloudWatch Logs and to an DynamoDB table.
- Get and display custom data from the DynamoDB table, then clean up resources.

SDK for Go V2

Serverless examples

Invoke a Lambda function from an Amazon MSK trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from an Amazon MSK cluster. The function retrieves the MSK payload and logs the record contents.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an Amazon MSK event with Lambda using Go.

```
package main

import (
 "encoding/base64"
 "fmt"

 "github.com/aws/aws-lambda-go/events"
 "github.com/aws/aws-lambda-go/lambda"
)

func handler(event events.KafkaEvent) {
 for key, records := range event.Records {
  fmt.Println("Key:", key)

  for _, record := range records {
   fmt.Println("Record:", record)
```

```
   decodedValue, _ := base64.StdEncoding.DecodeString(record.Value)
   message := string(decodedValue)
   fmt.Println("Message:", message)
  }
 }
}

func main() {
 lambda.Start(handler)
}
```

Partner Central examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Partner Central.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

`GetOpportunity`

The following code example shows how to use `GetOpportunity`.

SDK for Go V2

Get an opportunity.

```
package main

import (
```

```
 "context"
 "encoding/json"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/partnercentralselling"
)

func main() {
 config, err := config.LoadDefaultConfig(context.TODO())

 if err != nil {
  log.Fatal(err)
 }

 config.Region = "us-east-1"

 client := partnercentralselling.NewFromConfig(config)

 output, err := client.GetOpportunity(context.TODO(),
 &partnercentralselling.GetOpportunityInput{
  Identifier: aws.String("O1111111"),
  Catalog:    aws.String("AWS"),
 })

 if err != nil {
  log.Fatal(err)
 }
 log.Println("printing opportuniy...\n")

 jsonOutput, err := json.MarshalIndent(output, "", "    ")

 fmt.Println(string(jsonOutput))
}
```

- For API details, see GetOpportunity in *AWS SDK for Go API Reference*.

`ListOpportunities`

The following code example shows how to use `ListOpportunities`.

SDK for Go V2

List opportunities.

```
package main

import (
 "context"
 "encoding/json"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/partnercentralselling"
)

func main() {
 config, err := config.LoadDefaultConfig(context.TODO())

 if err != nil {
  log.Fatal(err)
 }

 config.Region = "us-east-1"

 client := partnercentralselling.NewFromConfig(config)

 output, err := client.ListOpportunities(context.TODO(),
 &partnercentralselling.ListOpportunitiesInput{
  MaxResults: aws.Int32(2),
  Catalog:    aws.String("AWS"),
 })

 if err != nil {
  log.Fatal(err)
 }

 jsonOutput, err := json.MarshalIndent(output, "", "    ")
 fmt.Println(string(jsonOutput))
}
```

- For API details, see ListOpportunities in *AWS SDK for Go API Reference*.

Amazon RDS examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon RDS.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon RDS

The following code examples show how to get started using Amazon RDS.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/rds"
)
```

```
// main uses the AWS SDK for Go V2 to create an Amazon Relational Database Service
 (Amazon RDS)
// client and list up to 20 DB instances in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 rdsClient := rds.NewFromConfig(sdkConfig)
 const maxInstances = 20
 fmt.Printf("Let's list up to %v DB instances.\n", maxInstances)
 output, err := rdsClient.DescribeDBInstances(ctx,
  &rds.DescribeDBInstancesInput{MaxRecords: aws.Int32(maxInstances)})
 if err != nil {
  fmt.Printf("Couldn't list DB instances: %v\n", err)
  return
 }
 if len(output.DBInstances) == 0 {
  fmt.Println("No DB instances found.")
 } else {
  for _, instance := range output.DBInstances {
   fmt.Printf("DB instance %v has database %v.\n", *instance.DBInstanceIdentifier,
    *instance.DBName)
  }
 }
}
```

- For API details, see DescribeDBInstances in *AWS SDK for Go API Reference*.

Basics

Learn the basics

The following code example shows how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.
- Take a snapshot of the instance.
- Delete the instance and parameter group.

SDK for Go V2

Serverless examples

Connecting to an Amazon RDS database in a Lambda function

The following code example shows how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Connecting to an Amazon RDS database in a Lambda function using Go.

```
/*
Golang v2 code here.
*/
```

```
package main

import (
 "context"
 "database/sql"
 "encoding/json"
 "fmt"
 "os"

 "github.com/aws/aws-lambda-go/lambda"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
 _ "github.com/go-sql-driver/mysql"
)

type MyEvent struct {
 Name string `json:"name"`
}

func HandleRequest(event *MyEvent) (map[string]interface{}, error) {

 var dbName string = os.Getenv("DatabaseName")

Amazon Redshift examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon Redshift.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Redshift

The following code examples show how to get started using Amazon Redshift.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/redshift"
)

// main uses the AWS SDK for Go V2 to create a Redshift client
// and list up to 10 clusters in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 redshiftClient := redshift.NewFromConfig(sdkConfig)
```

```
 count := 20
 fmt.Printf("Let's list up to %v clusters for your account.\n", count)
 result, err := redshiftClient.DescribeClusters(ctx,
 &redshift.DescribeClustersInput{
  MaxRecords: aws.Int32(int32(count)),
 })
 if err != nil {
  fmt.Printf("Couldn't list clusters for your account. Here's why: %v\n", err)
  return
 }
 if len(result.Clusters) == 0 {
  fmt.Println("You don't have any clusters!")
  return
 }
 for _, cluster := range result.Clusters {
  fmt.Printf("\t%v : %v\n", *cluster.ClusterIdentifier, *cluster.ClusterStatus)
 }
}
```

- For API details, see DescribeClusters in *AWS SDK for Go API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a Redshift cluster.
- List databases in the cluster.
- Create a table named Movies.
- Populate the Movies table.
- Query the Movies table by year.
- Modify the Redshift cluster.

- Delete the Amazon Redshift cluster.

Amazon S3 examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon S3.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon S3

The following code examples show how to get started using Amazon S3.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "errors"
 "fmt"

 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/s3"
 "github.com/aws/smithy-go"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Storage Service
// (Amazon S3) client and list up to 10 buckets in your account.

- Actions
- Scenarios
- Serverless examples

Basics

Learn the basics

The following code example shows how to:

- Create a bucket and upload a file to it.
- Download an object from a bucket.
- Copy an object to a subfolder in a bucket.
- List the objects in a bucket.
- Delete the bucket objects and the bucket.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Define a struct that wraps bucket and object actions used by the scenario.

Upload or download large files

The following code example shows how to upload or download large files to and from Amazon S3.

For more information, see Uploading an object using multipart upload.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create functions that use upload and download managers to break the data into parts and transfer them concurrently.

```
import (
 "bytes"
 "context"
 "errors"
 "fmt"
 "io"
 "log"
 "os"
 "time"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/feature/s3/manager"
 "github.com/aws/aws-sdk-go-v2/service/s3"
 "github.com/aws/aws-sdk-go-v2/service/s3/types"
 "github.com/aws/smithy-go"
)

// BucketBasics encapsulates the Amazon Simple Storage Service (Amazon S3) actions
// used in the examples.
// It contains S3Client, an Amazon S3 service client that is used to perform bucket
// and object actions.
type BucketBasics struct {
 S3Client *s3.Client
}

// UploadLargeObject uses an upload manager to upload data to an object in a bucket.
// The upload manager breaks large data into parts and uploads the parts
 concurrently.
```

```
func (basics BucketBasics) UploadLargeObject(ctx context.Context, bucketName string,
 objectKey string, largeObject []byte) error {
 largeBuffer := bytes.NewReader(largeObject)
 var partMiBs int64 = 10
 uploader := manager.NewUploader(basics.S3Client, func(u *manager.Uploader) {
  u.PartSize = partMiBs * 1024 * 1024
 })
 _, err := uploader.Upload(ctx, &s3.PutObjectInput{
  Bucket: aws.String(bucketName),
  Key:    aws.String(objectKey),
  Body:   largeBuffer,
 })
 if err != nil {
  var apiErr smithy.APIError
  if errors.As(err, &apiErr) && apiErr.ErrorCode() == "EntityTooLarge" {
   log.Printf("Error while uploading object to %s. The object is too large.\n"+
    "The maximum size for a multipart upload is 5TB.", bucketName)
  } else {
   log.Printf("Couldn't upload large object to %v:%v. Here's why: %v\n",
    bucketName, objectKey, err)
  }
 } else {
  err = s3.NewObjectExistsWaiter(basics.S3Client).Wait(
   ctx, &s3.HeadObjectInput{Bucket: aws.String(bucketName), Key:
 aws.String(objectKey)}, time.Minute)
  if err != nil {
   log.Printf("Failed attempt to wait for object %s to exist.\n", objectKey)
  }
 }

 return err
}

// DownloadLargeObject uses a download manager to download an object from a bucket.
// The download manager gets the data in parts and writes them to a buffer until all
 of
// the data has been downloaded.

Serverless examples

Invoke a Lambda function from an Amazon S3 trigger

The following code example shows how to implement a Lambda function that receives an event triggered by uploading an object to an S3 bucket. The function retrieves the S3 bucket name and object key from the event parameter and calls the Amazon S3 API to retrieve and log the content type of the object.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an S3 event with Lambda using Go.

```

 "github.com/aws/aws-lambda-go/lambda"
 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/s3"
)

func handler(ctx context.Context, s3Event events.S3Event) error {
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  log.Printf("failed to load default config: %s", err)
  return err
```

```
 }
 s3Client := s3.NewFromConfig(sdkConfig)

 for _, record := range s3Event.Records {
  bucket := record.S3.Bucket.Name
  key := record.S3.Object.URLDecodedKey
  headOutput, err := s3Client.HeadObject(ctx, &s3.HeadObjectInput{
   Bucket: &bucket,
   Key:    &key,
  })
  if err != nil {
   log.Printf("error getting head of object %s/%s: %s", bucket, key, err)
   return err
  }
  log.Printf("successfully retrieved %s/%s of type %s", bucket, key,
 *headOutput.ContentType)
 }

 return nil
}

func main() {
 lambda.Start(handler)
}
```

Amazon SNS examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon SNS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon SNS

The following code examples show how to get started using Amazon SNS.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/sns"
 "github.com/aws/aws-sdk-go-v2/service/sns/types"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Notification Service
// (Amazon SNS) client and list the topics in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 snsClient := sns.NewFromConfig(sdkConfig)
 fmt.Println("Let's list the topics for your account.")
 var topics []types.Topic
 paginator := sns.NewListTopicsPaginator(snsClient, &sns.ListTopicsInput{})
 for paginator.HasMorePages() {
```

```
  output, err := paginator.NextPage(ctx)
  if err != nil {
   log.Printf("Couldn't get topics. Here's why: %v\n", err)
   break
  } else {
   topics = append(topics, output.Topics...)
  }
 }
 if len(topics) == 0 {
  fmt.Println("You don't have any topics!")
 } else {
  for _, topic := range topics {
   fmt.Printf("\t%v\n", *topic.TopicArn)
  }
 }
}
```

- For API details, see ListTopics in *AWS SDK for Go API Reference*.

Topics

- Actions
- Scenarios
- Serverless examples

Actions

`CreateTopic`

The following code example shows how to use `CreateTopic`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/sns"
 "github.com/aws/aws-sdk-go-v2/service/sns/types"
)

// SnsActions encapsulates the Amazon Simple Notification Service (Amazon SNS)
 actions
// used in the examples.
type SnsActions struct {
 SnsClient *sns.Client
}

// CreateTopic creates an Amazon SNS topic with the specified name. You can
 optionally
// specify that the topic is created as a FIFO topic and whether it uses content-
based
// deduplication instead of ID-based deduplication.
func (actor SnsActions) CreateTopic(ctx context.Context, topicName string,
 isFifoTopic bool, contentBasedDeduplication bool) (string, error) {
 var topicArn string
 topicAttributes := map[string]string{}
 if isFifoTopic {
  topicAttributes["FifoTopic"] = "true"
 }
 if contentBasedDeduplication {
  topicAttributes["ContentBasedDeduplication"] = "true"
 }
 topic, err := actor.SnsClient.CreateTopic(ctx, &sns.CreateTopicInput{
  Name:       aws.String(topicName),
  Attributes: topicAttributes,
 })
 if err != nil {
  log.Printf("Couldn't create topic %v. Here's why: %v\n", topicName, err)
 } else {
  topicArn = *topic.TopicArn
```

```
 }

 return topicArn, err
}
```

- For API details, see CreateTopic in *AWS SDK for Go API Reference*.

`DeleteTopic`

The following code example shows how to use `DeleteTopic`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/sns"
 "github.com/aws/aws-sdk-go-v2/service/sns/types"
)

// SnsActions encapsulates the Amazon Simple Notification Service (Amazon SNS)
 actions
// used in the examples.
type SnsActions struct {
 SnsClient *sns.Client
}
```

```
// DeleteTopic delete an Amazon SNS topic.
func (actor SnsActions) DeleteTopic(ctx context.Context, topicArn string) error {
 _, err := actor.SnsClient.DeleteTopic(ctx, &sns.DeleteTopicInput{
  TopicArn: aws.String(topicArn)})
 if err != nil {
  log.Printf("Couldn't delete topic %v. Here's why: %v\n", topicArn, err)
 }
 return err
}
```

- For API details, see DeleteTopic in *AWS SDK for Go API Reference*.

`ListTopics`

The following code example shows how to use `ListTopics`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/sns"
 "github.com/aws/aws-sdk-go-v2/service/sns/types"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Notification Service
// (Amazon SNS) client and list the topics in your account.
```

```
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 snsClient := sns.NewFromConfig(sdkConfig)
 fmt.Println("Let's list the topics for your account.")
 var topics []types.Topic
 paginator := sns.NewListTopicsPaginator(snsClient, &sns.ListTopicsInput{})
 for paginator.HasMorePages() {
  output, err := paginator.NextPage(ctx)
  if err != nil {
   log.Printf("Couldn't get topics. Here's why: %v\n", err)
   break
  } else {
   topics = append(topics, output.Topics...)
  }
 }
 if len(topics) == 0 {
  fmt.Println("You don't have any topics!")
 } else {
  for _, topic := range topics {
   fmt.Printf("\t%v\n", *topic.TopicArn)
  }
 }
}
```

- For API details, see ListTopics in *AWS SDK for Go API Reference*.

`Publish`

The following code example shows how to use `Publish`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/sns"
 "github.com/aws/aws-sdk-go-v2/service/sns/types"
)

// SnsActions encapsulates the Amazon Simple Notification Service (Amazon SNS)
 actions
// used in the examples.
type SnsActions struct {
 SnsClient *sns.Client
}

// Publish publishes a message to an Amazon SNS topic. The message is then sent to
 all
// subscribers. When the topic is a FIFO topic, the message must also contain a
 group ID
// and, when ID-based deduplication is used, a deduplication ID. An optional key-
value
// filter attribute can be specified so that the message can be filtered according
 to
// a filter policy.
func (actor SnsActions) Publish(ctx context.Context, topicArn string, message
 string, groupId string, dedupId string, filterKey string, filterValue string) error
 {
 publishInput := sns.PublishInput{TopicArn: aws.String(topicArn), Message:
 aws.String(message)}
```

```
 if groupId != "" {
  publishInput.MessageGroupId = aws.String(groupId)
 }
 if dedupId != "" {
  publishInput.MessageDeduplicationId = aws.String(dedupId)
 }
 if filterKey != "" && filterValue != "" {
  publishInput.MessageAttributes = map[string]types.MessageAttributeValue{
   filterKey: {DataType: aws.String("String"), StringValue:
 aws.String(filterValue)},
  }
 }
 _, err := actor.SnsClient.Publish(ctx, &publishInput)
 if err != nil {
  log.Printf("Couldn't publish message to topic %v. Here's why: %v", topicArn, err)
 }
 return err
}
```

- For API details, see Publish in *AWS SDK for Go API Reference*.

`Subscribe`

The following code example shows how to use `Subscribe`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Subscribe a queue to a topic with optional filters.

```
import (
 "context"
 "encoding/json"
 "log"
```

```
 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/sns"
 "github.com/aws/aws-sdk-go-v2/service/sns/types"
)

// SnsActions encapsulates the Amazon Simple Notification Service (Amazon SNS)
 actions
// used in the examples.
type SnsActions struct {
 SnsClient *sns.Client
}

// SubscribeQueue subscribes an Amazon Simple Queue Service (Amazon SQS) queue to an
// Amazon SNS topic. When filterMap is not nil, it is used to specify a filter
 policy
// so that messages are only sent to the queue when the message has the specified
 attributes.
func (actor SnsActions) SubscribeQueue(ctx context.Context, topicArn string,
 queueArn string, filterMap map[string][]string) (string, error) {
 var subscriptionArn string
 var attributes map[string]string
 if filterMap != nil {
  filterBytes, err := json.Marshal(filterMap)
  if err != nil {
   log.Printf("Couldn't create filter policy, here's why: %v\n", err)
   return "", err
  }
  attributes = map[string]string{"FilterPolicy": string(filterBytes)}
 }
 output, err := actor.SnsClient.Subscribe(ctx, &sns.SubscribeInput{
  Protocol:              aws.String("sqs"),
  TopicArn:              aws.String(topicArn),
  Attributes:            attributes,
  Endpoint:              aws.String(queueArn),
  ReturnSubscriptionArn: true,
 })
 if err != nil {
  log.Printf("Couldn't susbscribe queue %v to topic %v. Here's why: %v\n",
   queueArn, topicArn, err)
 } else {
  subscriptionArn = *output.SubscriptionArn
```

```
 }

 return subscriptionArn, err
}
```

- For API details, see Subscribe in *AWS SDK for Go API Reference*.

Scenarios

Publish messages to queues

The following code example shows how to:

- Create topic (FIFO or non-FIFO).
- Subscribe several queues to the topic with an option to apply a filter.
- Publish messages to the topic.
- Poll the queues for messages received.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
import (
 "context"
 "encoding/json"
 "fmt"

Serverless examples

Invoke a Lambda function from an Amazon SNS trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving messages from an SNS topic. The function retrieves the messages from the event parameter and logs the content of each message.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an SNS event with Lambda using Go.

```

// SPDX-License-Identifier: Apache-2.0
package main

import (
 "context"
 "fmt"

 "github.com/aws/aws-lambda-go/events"
 "github.com/aws/aws-lambda-go/lambda"
)
```

```
func handler(ctx context.Context, snsEvent events.SNSEvent) {
 for _, record := range snsEvent.Records {
  processMessage(record)
 }
 fmt.Println("done")
}

func processMessage(record events.SNSEventRecord) {
 message := record.SNS.Message
 fmt.Printf("Processed message: %s\n", message)
 // TODO: Process your record here
}

func main() {
 lambda.Start(handler)
}
```

Amazon SQS examples using SDK for Go V2

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Go V2 with Amazon SQS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon SQS

The following code examples show how to get started using Amazon SQS.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/sqs"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Queue Service
// (Amazon SQS) client and list the queues in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")
  fmt.Println(err)
  return
 }
 sqsClient := sqs.NewFromConfig(sdkConfig)
 fmt.Println("Let's list the queues for your account.")
 var queueUrls []string
 paginator := sqs.NewListQueuesPaginator(sqsClient, &sqs.ListQueuesInput{})
 for paginator.HasMorePages() {
  output, err := paginator.NextPage(ctx)
  if err != nil {
   log.Printf("Couldn't get queues. Here's why: %v\n", err)
   break
```

```
  } else {
   queueUrls = append(queueUrls, output.QueueUrls...)
  }
 }
 if len(queueUrls) == 0 {

Actions

`CreateQueue`

The following code example shows how to use `CreateQueue`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
```

```
 "encoding/json"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/sqs"
 "github.com/aws/aws-sdk-go-v2/service/sqs/types"
)

// SqsActions encapsulates the Amazon Simple Queue Service (Amazon SQS) actions
// used in the examples.
type SqsActions struct {
 SqsClient *sqs.Client
}

// CreateQueue creates an Amazon SQS queue with the specified name. You can specify
// whether the queue is created as a FIFO queue.
func (actor SqsActions) CreateQueue(ctx context.Context, queueName string,
 isFifoQueue bool) (string, error) {
 var queueUrl string
 queueAttributes := map[string]string{}
 if isFifoQueue {
  queueAttributes["FifoQueue"] = "true"
 }
 queue, err := actor.SqsClient.CreateQueue(ctx, &sqs.CreateQueueInput{
  QueueName:  aws.String(queueName),
  Attributes: queueAttributes,
 })
 if err != nil {
  log.Printf("Couldn't create queue %v. Here's why: %v\n", queueName, err)
 } else {
  queueUrl = *queue.QueueUrl
 }

 return queueUrl, err
}
```

- For API details, see CreateQueue in *AWS SDK for Go API Reference*.

`DeleteMessageBatch`

The following code example shows how to use `DeleteMessageBatch`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/sqs"
 "github.com/aws/aws-sdk-go-v2/service/sqs/types"
)

// SqsActions encapsulates the Amazon Simple Queue Service (Amazon SQS) actions
// used in the examples.
type SqsActions struct {
 SqsClient *sqs.Client
}

// DeleteMessages uses the DeleteMessageBatch action to delete a batch of messages
 from
// an Amazon SQS queue.
func (actor SqsActions) DeleteMessages(ctx context.Context, queueUrl string,
 messages []types.Message) error {
 entries := make([]types.DeleteMessageBatchRequestEntry, len(messages))
 for msgIndex := range messages {
  entries[msgIndex].Id = aws.String(fmt.Sprintf("%v", msgIndex))
  entries[msgIndex].ReceiptHandle = messages[msgIndex].ReceiptHandle
 }
 _, err := actor.SqsClient.DeleteMessageBatch(ctx, &sqs.DeleteMessageBatchInput{
```

```
  Entries:  entries,
  QueueUrl: aws.String(queueUrl),
 })
 if err != nil {
  log.Printf("Couldn't delete messages from queue %v. Here's why: %v\n", queueUrl,
 err)
 }
 return err
}
```

- For API details, see DeleteMessageBatch in *AWS SDK for Go API Reference*.

`DeleteQueue`

The following code example shows how to use `DeleteQueue`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/sqs"
 "github.com/aws/aws-sdk-go-v2/service/sqs/types"
)

// SqsActions encapsulates the Amazon Simple Queue Service (Amazon SQS) actions
// used in the examples.
type SqsActions struct {
 SqsClient *sqs.Client
```

```
}

// DeleteQueue deletes an Amazon SQS queue.
func (actor SqsActions) DeleteQueue(ctx context.Context, queueUrl string) error {
 _, err := actor.SqsClient.DeleteQueue(ctx, &sqs.DeleteQueueInput{
  QueueUrl: aws.String(queueUrl)})
 if err != nil {
  log.Printf("Couldn't delete queue %v. Here's why: %v\n", queueUrl, err)
 }
 return err
}
```

- For API details, see DeleteQueue in *AWS SDK for Go API Reference*.

`GetQueueAttributes`

The following code example shows how to use `GetQueueAttributes`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import (
 "context"
 "encoding/json"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/service/sqs"
 "github.com/aws/aws-sdk-go-v2/service/sqs/types"
)
```

```
// SqsActions encapsulates the Amazon Simple Queue Service (Amazon SQS) actions
// used in the examples.
type SqsActions struct {
 SqsClient *sqs.Client
}

// GetQueueArn uses the GetQueueAttributes action to get the Amazon Resource Name
 (ARN)
// of an Amazon SQS queue.
func (actor SqsActions) GetQueueArn(ctx context.Context, queueUrl string) (string,
 error) {
 var queueArn string
 arnAttributeName := types.QueueAttributeNameQueueArn
 attribute, err := actor.SqsClient.GetQueueAttributes(ctx,
 &sqs.GetQueueAttributesInput{
  QueueUrl:       aws.String(queueUrl),
  AttributeNames: []types.QueueAttributeName{arnAttributeName},
 })
 if err != nil {
  log.Printf("Couldn't get ARN for queue %v. Here's why: %v\n", queueUrl, err)
 } else {
  queueArn = attribute.Attributes[string(arnAttributeName)]
 }
 return queueArn, err
}
```

- For API details, see GetQueueAttributes in *AWS SDK for Go API Reference*.

`ListQueues`

The following code example shows how to use `ListQueues`.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package main

import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/config"
 "github.com/aws/aws-sdk-go-v2/service/sqs"
)

// main uses the AWS SDK for Go V2 to create an Amazon Simple Queue Service
// (Amazon SQS) client and list the queues in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
 ctx := context.Background()
 sdkConfig, err := config.LoadDefaultConfig(ctx)
 if err != nil {
  fmt.Println("Couldn't load default configuration. Have you set up your AWS
 account?")

- For API details, see SetQueueAttributes in *AWS SDK for Go API Reference*.

Scenarios

Publish messages to queues

The following code example shows how to:

- Create topic (FIFO or non-FIFO).
- Subscribe several queues to the topic with an option to apply a filter.
- Publish messages to the topic.
- Poll the queues for messages received.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

Serverless examples

Invoke a Lambda function from an Amazon SQS trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving messages from an SQS queue. The function retrieves the messages from the event parameter and logs the content of each message.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an SQS event with Lambda using Go.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
package integration_sqs_to_lambda

import (
 "fmt"
 "github.com/aws/aws-lambda-go/events"
 "github.com/aws/aws-lambda-go/lambda"
)

func handler(event events.SQSEvent) error {
 for _, record := range event.Records {
  err := processMessage(record)
  if err != nil {
   return err
  }
 }
 fmt.Println("done")
 return nil
}

func processMessage(record events.SQSMessage) error {
 fmt.Printf("Processed message %s\n", record.Body)
 // TODO: Do interesting work based on the new message
 return nil
}

func main() {
 lambda.Start(handler)
}
```

Reporting batch item failures for Lambda functions with an Amazon SQS trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from an SQS queue. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Reporting SQS batch item failures with Lambda using Go.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
package main

import (
 "context"
 "encoding/json"
 "fmt"
 "github.com/aws/aws-lambda-go/events"
 "github.com/aws/aws-lambda-go/lambda"
)

func handler(ctx context.Context, sqsEvent events.SQSEvent) (map[string]interface{},
 error) {
 batchItemFailures := []map[string]interface{}{}

 for _, message := range sqsEvent.Records {

  if /* Your message processing condition here */ {
   batchItemFailures = append(batchItemFailures, map[string]interface{}
{"itemIdentifier": message.MessageId})
  }
 }

 sqsBatchResponse := map[string]interface{}{
  "batchItemFailures": batchItemFailures,
```

```
 }
 return sqsBatchResponse, nil
}

func main() {
 lambda.Start(handler)
}
```

Migrate to the AWS SDK for Go v2

Minimum Go Version

The AWS SDK for Go requires a minimum Go version of 1.20. The latest version of Go can be downloaded on the Downloads page. See the Release History for more information about each Go version release, and relevant information required for upgrading.

Modularization

The AWS SDK for Go has been updated to take advantage of the Go modules which became the default development mode in Go 1.13. A number of packages provided by the SDK have been modularized and are independently versioned and released respectively. This change enables improved application dependency modeling, and enables the SDK to provide new features and functionality that follows the Go module versioning strategy.

The following list are some Go modules provided by the SDK:

Module	Description
`github.com/aws/aws-sdk-go-v2`	The SDK core
`github.com/aws/aws-sdk-go-v2/config`	Shared Configuration Loading
`github.com/aws/aws-sdk-go-v2/credentials`	AWS Credential Providers
`github.com/aws/aws-sdk-go-v2/feature/ec2/imds`	Amazon EC2 Instance Metadata Service Client

The SDK's service clients and higher level utilities modules are nested under the following import paths:

Import Root	Description
`github.com/aws/aws-sdk-go-v2/service/`	Service Client Modules
`github.com/aws/aws-sdk-go-v2/feature/`	High-Level utilities for services like the Amazon S3 Transfer Manager

Configuration Loading

The session package and associated functionality are replaced with a simplified configuration system provided by the config package. The `config` package is a separate Go module, and can be included in your application's dependencies by with `go get`.

```
go get github.com/aws/aws-sdk-go-v2/config
```

The session.New, session.NewSession, NewSessionWithOptions, and session.Must must be migrated to config.LoadDefaultConfig.

The `config` package provides several helper functions that aid in overriding the shared configuration loading programmatically. These function names are prefixed with `With` followed by option that they override. Let's look at some examples of how to migrate usage of the `session` package.

For more information on loading shared configuration, see Configure the SDK.

Examples

Migrating from NewSession to LoadDefaultConfig

The following example shows how usage of `session.NewSession` without additional argument parameters is migrated to `config.LoadDefaultConfig`.

```
// V1 using NewSession

import "github.com/aws/aws-sdk-go/aws/session"

// ...
```

```
sess, err := session.NewSession()
if err != nil {
    // handle error
}
```

```
// V2 using LoadDefaultConfig

import "context"
import "github.com/aws/aws-sdk-go-v2/config"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    // handle error
}
```

Migrating from NewSession with aws.Config options

The example shows how to migrate overriding of `aws.Config` values during configuration loading. One or more `config.With*` helper functions can be provided to `config.LoadDefaultConfig` to override the loaded configuration values. In this example the AWS Region is overridden to `us-west-2` using the config.WithRegion helper function.

```
// V1

import "github.com/aws/aws-sdk-go/aws"
import "github.com/aws/aws-sdk-go/aws/session"

// ...

sess, err := session.NewSession(aws.Config{
    Region: aws.String("us-west-2")
})
if err != nil {
    // handle error
}
```

```
// V2
```

```
import "context"
import "github.com/aws/aws-sdk-go-v2/config"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO(),
    config.WithRegion("us-west-2"),
)
if err != nil {
    // handle error
}
```

Migrating from NewSessionWithOptions

This example shows how to migrate overriding values during configuration loading. Zero or more `config.With*` helper functions can be provided to `config.LoadDefaultConfig` to override the loaded configuration values. In this example we show how to override the target profile that is used when loading the AWS SDK shared configuration.

```
// V1

import "github.com/aws/aws-sdk-go/aws"
import "github.com/aws/aws-sdk-go/aws/session"

// ...

sess, err := session.NewSessionWithOptions(aws.Config{
    Profile: "my-application-profile"
})
if err != nil {
    // handle error
}
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/config"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO(),
    config.WithSharedConfigProfile("my-application-profile"),
```

```
)
if err != nil {
    // handle error
}
```

Mocking and `*iface`

The `*iface` packages and interfaces therein (e.g. s3iface.S3API) have been removed. These interface definitions are not stable since they are broken every time a service adds a new operation.

Usage of `*iface` should be replaced by scoped caller-defined interfaces for the service operations being used:

```
// V1

import "io"

import "github.com/aws/aws-sdk-go/service/s3"
import "github.com/aws/aws-sdk-go/service/s3/s3iface"

func GetObjectBytes(client s3iface.S3API, bucket, key string) ([]byte, error) {
    object, err := client.GetObject(&s3.GetObjectInput{
        Bucket: &bucket,
        Key:    &key,
    })
    if err != nil {
        return nil, err
    }
    defer object.Body.Close()

    return io.ReadAll(object.Body)
}
```

```
// V2

import "context"
import "io"

import "github.com/aws/aws-sdk-go-v2/service/s3"

type GetObjectAPIClient interface {
```

```
    GetObject(context.Context, *s3.GetObjectInput, ...func(*s3.Options))
 (*s3.GetObjectOutput, error)
}

func GetObjectBytes(ctx context.Context, client GetObjectAPIClient, bucket, key string)
 ([]byte, error) {
    object, err := client.GetObject(ctx, &s3.GetObjectInput{
        Bucket: &bucket,
        Key:    &key,
    })
    if err != nil {
        return nil, err
    }
    defer object.Body.Close()

    return io.ReadAll(object.Body)
}
```

See the Unit Testing with the AWS SDK for Go v2 for more information.

Credentials and Credential Providers

The aws/credentials package and associated credential providers have been relocated to the credentials package location. The `credentials` package is a Go module that you retrieve by using `go get`.

```
go get github.com/aws/aws-sdk-go-v2/credentials
```

The AWS SDK for Go v2 release updates the AWS Credential Providers to provide a consistent interface for retrieving AWS Credentials. Each provider implements the aws.CredentialsProvider interface, which defines a `Retrieve` method that returns a `(aws.Credentials, error)`. aws.Credentials that is analogous to the AWS SDK for Go v1 credentials.Value type.

You must wrap `aws.CredentialsProvider` objects with aws.CredentialsCache to allow credential caching to occur. You use NewCredentialsCache to construct a `aws.CredentialsCache` object. By default, credentials configured by `config.LoadDefaultConfig` are wrapped with `aws.CredentialsCache`.

The following table list the location changes of the AWS credential providers from AWS SDK for Go v1 to v2.

Name	V1 Import	V2 Import
Amazon EC2 IAM Role Credentials	`github.com/aws/aws-sdk-go/aws/credentials/ec2rolecreds`	`github.com/aws/aws-sdk-go-v2/credentials/ec2rolecreds`
Endpoint Credentials	`github.com/aws/aws-sdk-go/aws/credentials/endpointcreds`	`github.com/aws/aws-sdk-go-v2/credentials/endpointcreds`
Process Credentials	`github.com/aws/aws-sdk-go/aws/credentials/processcreds`	`github.com/aws/aws-sdk-go-v2/credentials/processcreds`
AWS Security Token Service	`github.com/aws/aws-sdk-go/aws/credentials/stscreds`	`github.com/aws/aws-sdk-go-v2/credentials/stscreds`

Static Credentials

Applications that use credentials.NewStaticCredentials to construct static credential programmatically must use credentials.NewStaticCredentialsProvider.

Example

```
// V1

import "github.com/aws/aws-sdk-go/aws/credentials"

// ...

appCreds := credentials.NewStaticCredentials(accessKey, secretKey, sessionToken)
value, err := appCreds.Get()
if err != nil {
    // handle error
}
```

```
// V2
```

```
import "context"
import "github.com/aws/aws-sdk-go-v2/aws"
import "github.com/aws/aws-sdk-go-v2/credentials"

// ...

appCreds := aws.NewCredentialsCache(credentials.NewStaticCredentialsProvider(accessKey,
 secretKey, sessionToken))
value, err := appCreds.Retrieve(context.TODO())
if err != nil {
    // handle error
}
```

Amazon EC2 IAM Role Credentials

You must migrate usage of NewCredentials and NewCredentialsWithClient to use New.

The `ec2rolecreds` package's `ec2rolecreds.New` takes functional options of ec2rolecreds.Options as input, allowing you override the specific Amazon EC2 Instance Metadata Service client to use, or to override the credential expiry window.

Example

```
// V1

import "github.com/aws/aws-sdk-go/aws/credentials/ec2rolecreds"

// ...

appCreds := ec2rolecreds.NewCredentials(sess)
value, err := appCreds.Get()
if err != nil {
    // handle error
}
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/aws"
import "github.com/aws/aws-sdk-go-v2/credentials/ec2rolecreds"

// ...
```

```
// New returns an object of a type that satisfies the aws.CredentialProvider interface
appCreds := aws.NewCredentialsCache(ec2rolecreds.New())
value, err := appCreds.Retrieve(context.TODO())
if err != nil {
    // handle error
}
```

Endpoint Credentials

You must migrate usage of NewCredentialsClient and NewProviderClient to use New.

The `endpointcreds` package's `New` function takes a string argument containing the URL of an HTTP or HTTPS endpoint to retrieve credentials from, and functional options of endpointcreds.Options to mutate the credentials provider and override specific configuration settings.

Process Credentials

You must migrate usage of NewCredentials, NewCredentialsCommand, and NewCredentialsTimeout to use NewProvider or NewProviderCommand.

The `processcreds` package's `NewProvider` function takes a string argument that is the command to be executed in the host environment's shell, and functional options of Options to mutate the credentials provider and override specific configuration settings.

`NewProviderCommand` takes an implementation of the NewCommandBuilder interface that defines more complex process commands that might take one or more command-line arguments, or have certain execution environment requirements. DefaultNewCommandBuilder implements this interface, and defines a command builder for a process that requires multiple command-line arguments.

Example

```
// V1

import "github.com/aws/aws-sdk-go/aws/credentials/processcreds"

// ...

appCreds := processcreds.NewCredentials("/path/to/command")
```

```
value, err := appCreds.Get()
if err != nil {
    // handle error
}
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/aws"
import "github.com/aws/aws-sdk-go-v2/credentials/processcreds"

// ...

appCreds := aws.NewCredentialsCache(processcreds.NewProvider("/path/to/command"))
value, err := appCreds.Retrieve(context.TODO())
if err != nil {
    // handle error
}
```

AWS Security Token Service Credentials

AssumeRole

You must migrate usage of NewCredentials, and NewCredentialsWithClient to use NewAssumeRoleProvider.

The `stscreds` package's `NewAssumeRoleProvider` function must be called with a sts.Client, and the AWS Identity and Access Management Role ARN to be assumed from the provided `sts.Client`'s configured credentials. You can also provide a set of functional options of AssumeRoleOptions to modify other optional settings of the provider.

Example

```
// V1

import "github.com/aws/aws-sdk-go/aws/credentials/stscreds"

// ...

appCreds := stscreds.NewCredentials(sess, "arn:aws:iam::123456789012:role/demo")
value, err := appCreds.Get()
if err != nil {
```

```
    // handle error
}
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/credentials/stscreds"
import "github.com/aws/aws-sdk-go-v2/service/sts"

// ...

client := sts.NewFromConfig(cfg)

appCreds := stscreds.NewAssumeRoleProvider(client, "arn:aws:iam::123456789012:role/
demo")
value, err := appCreds.Retrieve(context.TODO())
if err != nil {
    // handle error
}
```

AssumeRoleWithWebIdentity

You must migrate usage of NewWebIdentityCredentials, NewWebIdentityRoleProvider, and NewWebIdentityRoleProviderWithToken to use NewWebIdentityRoleProvider.

The `stscreds` package's `NewWebIdentityRoleProvider` function must be called with a sts.Client, and the AWS Identity and Access Management Role ARN to be assumed using the provided `sts.Client`'s configured credentials, and an implementation of a IdentityTokenRetriever for providing the OAuth 2.0 or OpenID Connect ID token. IdentityTokenFile is an `IdentityTokenRetriever` that can be used to provide the web identity token from a file located on the application's host file-system. You can also provide a set of functional options of WebIdentityRoleOptions to modify other optional settings for the provider.

Example

```
// V1

import "github.com/aws/aws-sdk-go/aws/credentials/stscreds"

// ...
```

```
appCreds := stscreds.NewWebIdentityRoleProvider(sess, "arn:aws:iam::123456789012:role/
demo", "sessionName", "/path/to/token")
value, err := appCreds.Get()
if err != nil {
    // handle error
}
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/aws"
import "github.com/aws/aws-sdk-go-v2/credentials/stscreds"
import "github.com/aws/aws-sdk-go-v2/service/sts"

// ...

client := sts.NewFromConfig(cfg)

appCreds := aws.NewCredentialsCache(stscreds.NewWebIdentityRoleProvider(
        client,
        "arn:aws:iam::123456789012:role/demo",
        stscreds.IdentityTokenFile("/path/to/file"),
        func(o *stscreds.WebIdentityRoleOptions) {
            o.RoleSessionName = "sessionName"
        }))
value, err := appCreds.Retrieve(context.TODO())
if err != nil {
    // handle error
}
```

Service Clients

AWS SDK for Go provides service client modules nested under the `github.com/aws/aws-sdk-go-v2/service` import path. Each service client is contained in a Go package using each service's unique identifier. The following table provides some examples of service import paths in the AWS SDK for Go.

Service Name	V1 Import Path	V2 Import Path
Amazon S3	`github.com/aws/aws-sdk-go/service/s3`	`github.com/aws/aws-sdk-go-v2/service/s3`
Amazon DynamoDB	`github.com/aws/aws-sdk-go/service/dynamodb`	`github.com/aws/aws-sdk-go-v2/service/dynamodb`
Amazon CloudWatch Logs	`github.com/aws/aws-sdk-go/service/cloudwatchlogs`	`github.com/aws/aws-sdk-go-v2/service/cloudwatchlogs`

Each service client package is an independently versioned Go module. To add the service client as a dependency of your application, use the `go get` command with the service's import path. For example, to add the Amazon S3 client to your dependencies use

```
go get github.com/aws/aws-sdk-go-v2/service/s3
```

Client Construction

You can construct clients in the AWS SDK for Go using either the `New` or `NewFromConfig` constructor functions in the client's package. When migrating from the AWS SDK for Go v1, we recommend that you use the `NewFromConfig` variant, which will return a new service client using values from an `aws.Config`. The `aws.Config` value will have been created while loading the SDK shared configuration using `config.LoadDefaultConfig`. For details on creating service clients, see Use the AWS SDK for Go v2 with AWS services.

Example 1

```
// V1

import "github.com/aws/aws-sdk-go/aws/session"
import "github.com/aws/aws-sdk-go/service/s3"

// ...

sess, err := session.NewSession()
```

```
if err != nil {
    // handle error
}

client := s3.New(sess)
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    // handle error
}

client := s3.NewFromConfig(cfg)
```

Example 2: Overriding Client Settings

```
// V1

import "github.com/aws/aws-sdk-go/aws"
import "github.com/aws/aws-sdk-go/aws/session"
import "github.com/aws/aws-sdk-go/service/s3"

// ...

sess, err := session.NewSession()
if err != nil {
    // handle error
}

client := s3.New(sess, &aws.Config{
    Region: aws.String("us-west-2"),
})
```

```
// V2
```

```
import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    // handle error
}

client := s3.NewFromConfig(cfg, func(o *s3.Options) {
    o.Region = "us-west-2"
})
```

Endpoints

The endpoints package no longer exists in the AWS SDK for Go. Each service client now embeds its required AWS endpoint metadata within the client package. This reduces the overall binary size of compiled applications by no longer including endpoint metadata for services not used by your application.

Additionally, each service now exposes its own interface for endpoint resolution in `EndpointResolverV2`. Each API takes a unique set of parameters for a service `EndpointParameters`, the values of which are sourced by the SDK from various locations when an operation is invoked.

By default, service clients use their configured AWS Region to resolve the service endpoint for the target Region. If your application requires a custom endpoint, you can specify custom behavior on `EndpointResolverV2` field on the `aws.Config` structure. If your application implements a custom endpoints.Resolver you must migrate it to conform to this new per-service interface.

For more information on endpoints and implementing a custom resolver, see Configure Client Endpoints.

Authentication

The AWS SDK for Go supports more advanced authentication behavior, which enables the use of newer AWS service features such as codecatalyst and S3 Express One Zone. Additionally, this behavior can be customized on a per-client basis.

Invoking API Operations

The number of service client operation methods have been reduced significantly. The `<OperationName>Request`, `<OperationName>WithContext`, and `<OperationName>` methods have all been consolidated into single operation method, `<OperationName>`.

Example

The following example shows how calls to the Amazon S3 PutObject operation would be migrated from AWS SDK for Go v1 to v2.

```
// V1

import "context"
import "github.com/aws/aws-sdk-go/service/s3"

// ...

client := s3.New(sess)

// Pattern 1
output, err := client.PutObject(&s3.PutObjectInput{
    // input parameters
})

// Pattern 2
output, err := client.PutObjectWithContext(context.TODO(), &s3.PutObjectInput{
    // input parameters
})

// Pattern 3
req, output := client.PutObjectRequest(context.TODO(), &s3.PutObjectInput{
    // input parameters
})
err := req.Send()
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...
```

```
client := s3.NewFromConfig(cfg)

output, err := client.PutObject(context.TODO(), &s3.PutObjectInput{
    // input parameters
})
```

Service Data Types

The top-level input and output types of an operation are found in the service client package. The input and output type for a given operation follow the pattern of `<OperationName>Input` and `<OperationName>Output`, where `OperationName` is the name of the operation you are invoking. For example, the input and output shape for the Amazon S3 PutObject operation are PutObjectInput and PutObjectOutput respectively.

All other service data types, other than input and output types, have been migrated to the `types` package located under the service client package import path hierarchy. For example, the s3.AccessControlPolicy type is now located at types.AccessControlPolicy.

Enumeration Values

The SDK now provides a typed experience for all API enumeration fields. Rather than using a string literal value copied from the service API reference documentation, you can now use one of the concrete types found in the service client's `types` package. For example, you can provide the Amazon S3 PutObjectInput operation with an ACL to be applied on an object. In the AWS SDK for Go v1, this parameter was a `*string` type. In the AWS SDK for Go, this parameter is now a types.ObjectCannedACL. The `types` package provides generated constants for the valid enumeration values that can be assigned to this field. For example types.ObjectCannedACLPrivate is the constant for the "private" canned ACL value. This value can be used in place of managing string constants within your application.

Pointer Parameters

The AWS SDK for Go v1 required pointer references to be passed for all input parameters to service operations. The AWS SDK for Go v2 has simplified the experience with most services by removing the need to pass input values as pointers where possible. This change means that many service clients operations no longer require your application to pass pointer references for the following types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`, `float32`, `float64`, `bool`. Similarly, slice

and map element types have been updated accordingly to reflect whether their elements must be passed as pointer references.

The aws package contains helper functions for creating pointers for the Go built-in types, these helpers should be used to more easily handle creating pointer types for these Go types. Similarly, helper methods are provided for safely de-referencing pointer values for these types. For example, the aws.String function converts from `string` ⇒ `*string`. Inversely, the aws.ToString converts from `*string` ⇒ `string`. When upgrading your application from AWS SDK for Go v1 to v2, you must migrate usage of the helpers for converting from the pointer types to the non-pointer variants. For example, aws.StringValue must be updated to `aws.ToString`.

Errors Types

The AWS SDK for Go takes full advantage of the error wrapping functionality introduced in Go 1.13. Services that model error responses have generated types available in their client's `types` package that can be used to test whether a client operation error was caused by one of these types. For example, Amazon S3 `GetObject` operation can return a `NoSuchKey` error if attempting to retrieve an object key that doesn't exist. You can use errors.As to test whether the returned operation error is a types.NoSuchKey error. In the event a service does not model a specific type for an error, you can utilize the smithy.APIError interface type for inspecting the returned error code and message from the service. This functionality replaces awserr.Error and the other awserr functionality from the AWS SDK for Go v1. For more details information on handling errors, see Handling Errors in the AWS SDK for Go V2.

Example

```
// V1

import "github.com/aws/aws-sdk-go/aws/awserr"
import "github.com/aws/aws-sdk-go/service/s3"

// ...

client := s3.New(sess)

output, err := s3.GetObject(&s3.GetObjectInput{
    // input parameters
})
if err != nil {
    if awsErr, ok := err.(awserr.Error); ok {
```

```
        if awsErr.Code() == "NoSuchKey" {
            // handle NoSuchKey
        } else {
            // handle other codes
        }
        return
    }
    // handle a error
}
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/service/s3"
import "github.com/aws/aws-sdk-go-v2/service/s3/types"
import "github.com/aws/smithy-go"

// ...

client := s3.NewFromConfig(cfg)

output, err := client.GetObject(context.TODO(), &s3.GetObjectInput{
    // input parameters
})
if err != nil {
    var nsk *types.NoSuchKey
    if errors.As(err, &nsk) {
        // handle NoSuchKey error
        return
    }
    var apiErr smithy.APIError
    if errors.As(err, &apiErr) {
        code := apiErr.ErrorCode()
        message := apiErr.ErrorMessage()
        // handle error code
        return
    }
    // handle error
    return
}
```

Paginators

Service operation paginators are no longer invoked as methods on the service client. To use a paginator for an operation you must construct a paginator for an operation using one of the paginator constructor methods. For example, to use paginate over the Amazon S3 `ListObjectsV2` operation you must construct its paginator using the s3.NewListObjectsV2Paginator. This constructor returns a ListObjectsV2Paginator which provides the methods `HasMorePages`, and `NextPage` for determining whether there are more pages to retrieve and invoking the operation to retrieve the next page respectively. More details on using the SDK paginators can be found at Using Operation Paginators.

Let's look at an example of how to migrate from a AWS SDK for Go v1 paginator to the AWS SDK for Go v2 equivalent.

Example

```
// V1

import "fmt"
import "github.com/aws/aws-sdk-go/service/s3"

// ...

client := s3.New(sess)

params := &s3.ListObjectsV2Input{
    // input parameters
}

totalObjects := 0
err := client.ListObjectsV2Pages(params, func(output *s3.ListObjectsV2Output, lastPage
 bool) bool {
    totalObjects += len(output.Contents)
    return !lastPage
})
if err != nil {
    // handle error
}
fmt.Println("total objects:", totalObjects)
```

```
// V2
```

```
import "context"
import "fmt"
import "github.com/aws/aws-sdk-go-v2/service/s3"

// ...

client := s3.NewFromConfig(cfg)

params := &s3.ListObjectsV2Input{
    // input parameters
}

totalObjects := 0
paginator := s3.NewListObjectsV2Paginator(client, params)
for paginator.HasMorePages() {
    output, err := paginator.NextPage(context.TODO())
    if err != nil {
        // handle error
    }
    totalObjects += len(output.Contents)
}
fmt.Println("total objects:", totalObjects)
```

Waiters

Service operation waiters are no longer invoked as methods on the service client. To use a waiter you first construct the desired waiter type, and then invoke the wait method. For example, to wait for a Amazon S3 Bucket to exist, you must construct a `BucketExists` waiter. Use the s3.NewBucketExistsWaiter constructor to create a s3.BucketExistsWaiter. The `s3.BucketExistsWaiter` provides a `Wait` method which can be used to wait for a bucket to become available.

Presigned Requests

The V1 SDK technically supported presigning *any* AWS SDK operation, however, this does not accurately represent what is actually supported at the service level (and in reality most AWS service operations do not support presigning).

AWS SDK for Go resolves this by exposing specific `PresignClient` implementations in service packages with specific APIs for supported presignable operations.

Note: If a service is missing presigning support for an operation that you were successfully using in SDK v1, please let us know by filing an issue on GitHub.

Uses of Presign and PresignRequest must be converted to use service-specific presigning clients.

The following example shows how to migrate presigning of an S3 GetObject request:

```
// V1

import (
    "fmt"
    "time"

    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/s3"
)

func main() {
    sess := session.Must(session.NewSessionWithOptions(session.Options{
        SharedConfigState: session.SharedConfigEnable,
    }))

    svc := s3.New(sess)
    req, _ := svc.GetObjectRequest(&s3.GetObjectInput{
        Bucket: aws.String("amzn-s3-demo-bucket"),
        Key:    aws.String("key"),
    })

    // pattern 1
    url1, err := req.Presign(20 * time.Minute)
    if err != nil {
        panic(err)
    }
    fmt.Println(url1)

    // pattern 2
    url2, header, err := req.PresignRequest(20 * time.Minute)
    if err != nil {
        panic(err)
    }
    fmt.Println(url2, header)
}
```

```
// V2

import (
    "context"
    "fmt"
    "time"

    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
)

func main() {
    cfg, err := config.LoadDefaultConfig(context.Background())
    if err != nil {
        panic(err)
    }

    svc := s3.NewPresignClient(s3.NewFromConfig(cfg))
    req, err := svc.PresignGetObject(context.Background(), &s3.GetObjectInput{
        Bucket: aws.String("amzn-s3-demo-bucket"),
        Key:    aws.String("key"),
    }, func(o *s3.PresignOptions) {
        o.Expires = 20 * time.Minute
    })
    if err != nil {
        panic(err)
    }

    fmt.Println(req.Method, req.URL, req.SignedHeader)
}
```

Request customization

The monolithic request.Request API has been re-compartmentalized.

Operation input/output

The opaque `Request` fields `Params` and `Data`, which hold the operation input and output structures respectively, are now accessible within specific middleware phases as input/output:

Request handlers which reference `Request.Params` and `Request.Data` must be migrated to middleware.

migrating `Params`

```
// V1

import (
    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/request"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/s3"
)

func withPutObjectDefaultACL(acl string) request.Option {
    return func(r *request.Request) {
        in, ok := r.Params.(*s3.PutObjectInput)
        if !ok {
            return
        }

        if in.ACL == nil {
            in.ACL = aws.String(acl)
        }
        r.Params = in
    }
}

func main() {
    sess := session.Must(session.NewSession())

 sess.Handlers.Validate.PushBack(withPutObjectDefaultACL(s3.ObjectCannedACLBucketOwnerFullContr

    // ...
}
```

```
// V2

import (
    "context"

    "github.com/aws/aws-sdk-go-v2/service/s3"
    "github.com/aws/aws-sdk-go-v2/service/s3/types"
```

```
    "github.com/aws/smithy-go/middleware"
    smithyhttp "github.com/aws/smithy-go/transport/http"
)

type withPutObjectDefaultACL struct {
    acl types.ObjectCannedACL
}

// implements middleware.InitializeMiddleware, which runs BEFORE a request has
// been serialized and can act on the operation input
var _ middleware.InitializeMiddleware = (*withPutObjectDefaultACL)(nil)

func (*withPutObjectDefaultACL) ID() string {
    return "withPutObjectDefaultACL"
}

func (m *withPutObjectDefaultACL) HandleInitialize(ctx context.Context, in
 middleware.InitializeInput, next middleware.InitializeHandler) (
    out middleware.InitializeOutput, metadata middleware.Metadata, err error,
) {
    input, ok := in.Parameters.(*s3.PutObjectInput)
    if !ok {
        return next.HandleInitialize(ctx, in)
    }

    if len(input.ACL) == 0 {
        input.ACL = m.acl
    }
    in.Parameters = input
    return next.HandleInitialize(ctx, in)
}

// create a helper function to simplify instrumentation of our middleware
func WithPutObjectDefaultACL(acl types.ObjectCannedACL) func (*s3.Options) {
    return func(o *s3.Options) {
        o.APIOptions = append(o.APIOptions, func (s *middleware.Stack) error {
            return s.Initialize.Add(&withPutObjectDefaultACL{acl: acl},
 middleware.After)
        })
    }
}

func main() {
    cfg, err := config.LoadDefaultConfig(context.Background())
```

```
    if err != nil {
        // ...
    }

    svc := s3.NewFromConfig(cfg,
 WithPutObjectDefaultACL(types.ObjectCannedACLBucketOwnerFullControl))
    // ...
}
```

migrating `Data`

```
// V1

import (
    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/request"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/s3"
)

func readPutObjectOutput(r *request.Request) {
        output, ok := r.Data.(*s3.PutObjectOutput)
        if !ok {
            return
        }

        // ...
    }
}

func main() {
    sess := session.Must(session.NewSession())
    sess.Handlers.Unmarshal.PushBack(readPutObjectOutput)

    svc := s3.New(sess)
    // ...
}
```

```
// V2

import (
    "context"
```

```
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
    "github.com/aws/smithy-go/middleware"
    smithyhttp "github.com/aws/smithy-go/transport/http"
)

type readPutObjectOutput struct{}

var _ middleware.DeserializeMiddleware = (*readPutObjectOutput)(nil)

func (*readPutObjectOutput) ID() string {
    return "readPutObjectOutput"
}

func (*readPutObjectOutput) HandleDeserialize(ctx context.Context, in
 middleware.DeserializeInput, next middleware.DeserializeHandler) (
    out middleware.DeserializeOutput, metadata middleware.Metadata, err error,
) {
    out, metadata, err = next.HandleDeserialize(ctx, in)
    if err != nil {
        // ...
    }

    output, ok := in.Parameters.(*s3.PutObjectOutput)
    if !ok {
        return out, metadata, err
    }

    // inspect output...

    return out, metadata, err
}

func WithReadPutObjectOutput(o *s3.Options) {
    o.APIOptions = append(o.APIOptions, func (s *middleware.Stack) error {
        return s.Initialize.Add(&withReadPutObjectOutput{}, middleware.Before)
    })
}

func main() {
    cfg, err := config.LoadDefaultConfig(context.Background())
    if err != nil {
        // ...
    }
```

```
    svc := s3.NewFromConfig(cfg, WithReadPutObjectOutput)
    // ...
}
```

HTTP request/response

The HTTPRequest and HTTPResponse fields from Request are now exposed in specific middleware phases. Since middleware is transport-agnostic, you must perform a type assertion on the middleware input or output to reveal the underlying HTTP request or response.

Request handlers which reference Request.HTTPRequest and Request.HTTPResponse must be migrated to middleware.

migrating HTTPRequest

```
// V1

import (
    "github.com/aws/aws-sdk-go/aws/request"
    "github.com/aws/aws-sdk-go/aws/session"
)

func withHeader(header, val string) request.Option {
    return func(r *request.Request) {
        request.HTTPRequest.Header.Set(header, val)
    }
}

func main() {
    sess := session.Must(session.NewSession())
    sess.Handlers.Build.PushBack(withHeader("x-user-header", "..."))

    svc := s3.New(sess)
    // ...
}
```

```
// V2

import (
    "context"
    "fmt"
```

```
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/s3"
    "github.com/aws/smithy-go/middleware"
    smithyhttp "github.com/aws/smithy-go/transport/http"
)

type withHeader struct {
    header, val string
}

// implements middleware.BuildMiddleware, which runs AFTER a request has been
// serialized and can operate on the transport request
var _ middleware.BuildMiddleware = (*withHeader)(nil)

func (*withHeader) ID() string {
    return "withHeader"
}

func (m *withHeader) HandleBuild(ctx context.Context, in middleware.BuildInput, next
 middleware.BuildHandler) (
    out middleware.BuildOutput, metadata middleware.Metadata, err error,
) {
    req, ok := in.Request.(*smithyhttp.Request)
    if !ok {
        return out, metadata, fmt.Errorf("unrecognized transport type %T", in.Request)
    }

    req.Header.Set(m.header, m.val)
    return next.HandleBuild(ctx, in)
}

func WithHeader(header, val string) func (*s3.Options) {
    return func(o *s3.Options) {
        o.APIOptions = append(o.APIOptions, func (s *middleware.Stack) error {
            return s.Build.Add(&withHeader{
                header: header,
                val: val,
            }, middleware.After)
        })
    }
}

func main() {
```

```
    cfg, err := config.LoadDefaultConfig(context.Background())
    if err != nil {
        // ...
    }

    svc := s3.NewFromConfig(cfg, WithHeader("x-user-header", "..."))
    // ...
}
```

Handler phases

SDK v2 middleware phases are the successor to v1 handler phases.

The following table provides a rough mapping of v1 handler phases to their equivalent location within the V2 middleware stack:

v1 handler name	v2 middleware phase
Validate	Initialize
Build	Serialize
Sign	Finalize
Send	n/a (1)
ValidateResponse	Deserialize
Unmarshal	Deserialize
UnmarshalMetadata	Deserialize
UnmarshalError	Deserialize
Retry	Finalize, after `"Retry"` middleware (2)
AfterRetry	Finalize, before `"Retry"` middleware, post-`next.HandleFinalize()` (2,3)
CompleteAttempt	Finalize, end of step

v1 handler name	v2 middleware phase
Complete	Initialize, start of step, post-`next.HandleInitialize()` (3)

(1) The Send phase in v1 is effectively the wrapped HTTP client round-trip in v2. This behavior is controlled by the `HTTPClient` field on client options.

(2) Any middleware after the `"Retry"` middleware in the Finalize step will be part of the retry loop.

(3) The middleware "stack" at operation time is built into a repeatedly-decorated handler function. Each handler is responsible for calling the next one in the chain. This implicitly means that a middleware step can also take action AFTER its next step has been called.

For example, for the Initialize step, which is at the top of the stack, this means Initialize middlewares that take action after calling the next handler effectively operate at the end of the request:

```
// V2

import (
    "context"

    "github.com/aws/smithy-go/middleware"
)

type onComplete struct{}

var _ middleware.InitializeMiddleware = (*onComplete)(nil)

func (*onComplete) ID() string {
    return "onComplete"
}

func (*onComplete) HandleInitialize(ctx context.Context, in middleware.InitializeInput,
 next middleware.InitializeHandler) (
    out middleware.InitializeOutput, metadata middleware.Metadata, err error,
) {
    out, metadata, err = next.HandleInitialize(ctx, in)
```

```
    // the entire operation was invoked above - the deserialized response is
    // available opaquely in out.Result, run post-op actions here...

    return out, metadata, err
}
```

Features

Amazon EC2 Instance Metadata Service

The AWS SDK for Go provides an Amazon EC2 Instance Metadata Service (IMDS) client that you can use to query the local IMDS when executing your application on an Amazon EC2 instance. The IMDS client is a separate Go module that can be added to your application by using

```
go get github.com/aws/aws-sdk-go-v2/feature/ec2/imds
```

The client constructor and method operations have been updated to match the design of the other SDK service clients.

Example

```
// V1

import "github.com/aws/aws-sdk-go/aws/ec2metadata"

// ...

client := ec2metadata.New(sess)

region, err := client.Region()
if err != nil {
    // handle error
}
```

```
// V2

import "context"
import "github.com/aws/aws-sdk-go-v2/feature/ec2/imds"

// ...
```

```
client := imds.NewFromConfig(cfg)

region, err := client.GetRegion(context.TODO())
if err != nil {
    // handle error
}
```

Amazon S3 Transfer Manager

The Amazon S3 transfer manager is available for managing uploads and downloads of objects concurrently. This package is located in a Go module outside the service client import path. This module can be retrieved by using `go get github.com/aws/aws-sdk-go-v2/feature/s3/manager`.

s3.NewUploader and s3.NewUploaderWithClient have been replaced with the constructor method manager.NewUploader for creating an Upload manager client.

s3.NewDownloader and s3.NewDownloaderWithClient have been replaced with a single constructor method manager.NewDownloader for creating a Download manager client.

Amazon CloudFront Signing Utilities

The AWS SDK for Go provides Amazon CloudFront signing utilities in a Go module outside the service client import path. This module can be retrieved by using `go get`.

```
go get github.com/aws/aws-sdk-go-v2/feature/cloudfront/sign
```

Amazon S3 Encryption Client

Starting in AWS SDK for Go, the Amazon S3 encryption client is a separate module under AWS Crypto Tools. The latest version of the S3 encryption client for Go, 3.x, is now available at https://github.com/aws/amazon-s3-encryption-client-go. This module can be retrieved by using `go get`:

```
go get github.com/aws/amazon-s3-encryption-client-go/v3
```

The separate `EncryptionClient` (v1, v2) and `DecryptionClient` (v1, v2) APIs have been replaced with a single client, S3EncryptionClientV3, that exposes both encrypt and decrypt functionality.

Like other service clients in AWS SDK for Go, the operation APIs have been condensed:

- The `GetObject`, `GetObjectRequest`, and `GetObjectWithContext` decryption APIs are replaced by GetObject.
- The `PutObject`, `PutObjectRequest`, and `PutObjectWithContext` encryption APIs are replaced by PutObject.

To learn how to migrate to the 3.x major version of the encryption client, see this guide.

Service Customizations Changes

Amazon S3

When migrating from AWS SDK for Go v1 to v2, an important change to be aware of involves the handling of the `SSECustomerKey` used for server-side encryption with customer-provided keys (SSE-C). In AWS SDK for Go v1, the encoding of the `SSECustomerKey` to Base64 was handled internally by the SDK. In SDK v2, this automatic encoding has been removed, and it is now required to manually encode the `SSECustomerKey` to Base64 before passing it to the SDK.

Example Adjustment:

```
// V1

import (
  "context"
  "encoding/base64"
  "github.com/aws/aws-sdk-go-v2/config"
  "github.com/aws/aws-sdk-go-v2/service/s3"
)
// ... more code

plainTextKey := "12345678901234567890123456789012" // 32 bytes in length

// calculate md5..

_, err = client.PutObjectWithContext(context.Background(), &s3.PutObjectInput{
    Bucket: aws.String("amzn-s3-demo-bucket"),
    Key:    aws.String("your-object-key"),
    Body:                 strings.NewReader("hello-world"),
    SSECustomerKey:       &plainTextKey,
```

```
    SSECustomerKeyMD5:    &base64Md5,
    SSECustomerAlgorithm: aws.String("AES256"),
})

// ... more code
```

```
// V2

import (
  "github.com/aws/aws-sdk-go/aws"
  "github.com/aws/aws-sdk-go/aws/session"
  "github.com/aws/aws-sdk-go/service/s3"
)

// ... more code

plainTextKey := "12345678901234567890123456789012" // 32 bytes in length
base64EncodedKey := base64.StdEncoding.EncodeToString([]byte(plainTextKey))

// calculate md5..

_, err = client.PutObject(context.Background(), &s3.PutObjectInput{
    Bucket: aws.String("amzn-s3-demo-bucket"),
    Key:    aws.String("your-object-key"),
    Body:                 strings.NewReader("hello-world"),
    SSECustomerKey:       &base64EncodedKey,
    SSECustomerKeyMD5:    &base64Md5,
    SSECustomerAlgorithm: aws.String("AES256"),
})

// ... more code
```

Security in AWS SDK for Go

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to AWS SDK for Go, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using AWS SDK for Go. The following topics show you how to configure AWS SDK for Go to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your AWS SDK for Go resources.

Topics

Data protection in AWS SDK for Go

The AWS shared responsibility model applies to data protection in AWS SDK for Go. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ.

For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with AWS SDK for Go or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Compliance validation for AWS SDK for Go

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security Compliance & Governance – These solution implementation guides discuss architectural considerations and provide steps for deploying security and compliance features.
- HIPAA Eligible Services Reference – Lists HIPAA eligible services. Not all AWS services are HIPAA eligible.
- AWS Compliance Resources – This collection of workbooks and guides might apply to your industry and location.
- AWS Customer Compliance Guides – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
- Evaluating Resources with Rules in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
- Amazon GuardDuty – This AWS service detects potential threats to your AWS accounts, workloads, containers, and data by monitoring your environment for suspicious and malicious activities. GuardDuty can help you address various compliance requirements, like PCI DSS, by meeting intrusion detection requirements mandated by certain compliance frameworks.
- AWS Audit Manager – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Resilience in AWS SDK for Go

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones

without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Document history for the AWS SDK for Go v2 Developer Guide

The following table describes the documentation releases for AWS SDK for Go v2.

Change	Description	Date
HTTP Interceptors	New section covering HTTP interceptors, their advantages over middleware, available hooks, and registration methods.	September 4, 2025
Data integrity protection with checksums	Content updated with details about automatic checksum calculation.	January 16, 2025
Initial release	Initial release of the AWS SDK for Go v2 Developer Guide	October 31, 2024
